## [SPECIFICATION]

## THERMAL DECOMPOSITION APPARATUS FOR WASTES

[TECHNICAL FIELD]

RECEIVED

FEB 2 2001

TC 1700

5

The present invention relates <sup>generally</sup> to thermal decomposition apparatus

for thermally decomposing various wastes which contain general wastes including polymer <sup>ones</sup> of resins, industrial wastes, infectious medical wastes, and chemical substances such as PCBs and waste oils without producing <sup>any</sup> gas containing harmful substances.

10

## BACKGROUND [ART] OF THE INVENTION

(counter &amp; underlie)

In the current society, an enormous amount of wastes are discharged daily and their disposal is a great problem. The wastes include various kinds <sup>of wastes</sup> such as general, industrial and medical <sup>wastes</sup> <sup>ones</sup>. Most of them <sup>wastes</sup> are processed by burning or <sup>burial</sup> burying them, which has several problems.

15

The <sup>primary</sup> ~~maximum~~ problem with the burning process is <sup>the production</sup> ~~that~~ harmful substances <sup>are produced by burning the wastes</sup>. In the burning process, the wastes are burnt <sup>with fed</sup> air. Thus, harmful substances such as soot, dust, carbon <sup>monoxide</sup> dioxide and nitrogen compound such as NO<sub>x</sub> are produced and discharged with other exhaust gas. Since the burning temperature <sup>is</sup> at about 700-800 °C, harmful dioxin <sup>is</sup> would be necessarily produced <sup>more or less</sup>, and hence exhaust gas and ashes containing dioxin <sup>would be</sup> are produced.

20

25

The harmful substance content of the exhaust gas is regulated <sup>globally</sup>. Especially, <sup>substances such as</sup> dioxin <sup>which</sup> has <sup>a</sup> very high toxicity <sup>and</sup> <sup>which</sup> adversely affects <sup>the</sup> human bodies for a long time <sup>and its discharge is strictly regulated</sup>.

RECEIVED

FEB -7 2001

TC 1700 MAIL ROOM

In order to prevent production of dioxin, the following measures *are available*  
 [have been taken mainly]:

(1) The wastes which produce no dioxin are segregated from the  
 ones which produce dioxin, and only the ones which produce no dioxin are  
 5 burnt<sup>ed</sup> *is used*

(2) A device<sub>1</sub> for removing dioxin contained in the exhaust gas  
 discharged from an incinerator<sub>1</sub> *and* is attached to an incinerator; *and* *or*

(3) An incinerator which burns wastes at [such] a high temperature *such*  
 that dioxin is difficult to produce (hereinafter referred to as a high  
 10 temperature incinerator) is used.

There is, however, the problem with the *first* ~~above~~ method<sup>in</sup> (1) *that* it  
 takes time and costs considerably *more* to segregate the wastes. In addition, it  
 is substantially impossible to perfectly separating<sup>e</sup> the wastes, and  
 production of a small amount of dioxin cannot be avoided.

15 The *second* ~~above~~ method<sup>2</sup> (2) is insufficient to cope with dioxin because *[a]* *there are presently*  
 no device<sup>s</sup> capable of completely removing dioxin *[is]* not put to practical use at  
 present<sup>y</sup>. Thus, it is insufficient to cope with dioxin. Thus, a secondary  
 incinerator<sub>1</sub> *is required* for burning dioxin contained in the exhaust gas, a cooling  
 device for rapidly cooling the exhaust gas so as not to reproduce dioxin, and  
 20 a *bug* filter for removing dioxin remaining in the exhaust gas are installed  
*on* [very often] *in* the incinerator. However, installation of such devices in  
 combination *is costly* requires a high cost<sup>y</sup> and renders *a more complicated* the incinerator *[complicated]*.

As described above, the exhaust gas contains a plurality of harmful  
 substances in addition to dioxin. In order to eliminate them all, a  
 25 plurality of devices for removing such harmful substances <sup>15</sup> *[are]* required to  
 be attached to the incinerator. Thus, the incinerator would become  
 expensive and complicated *structuro* *[composition]*.

Since the high temperature incinerator is expensive, there is <sup>the</sup> a problem with the <sup>third</sup> ~~above~~ method <sup>replace</sup> (3) that it is not easy to ~~destroy~~ the old incinerator <sup>with a</sup> and to ~~newly~~ build up a high temperature incinerator. In addition, it is difficult to completely prevent production of even a small amount of dioxin even <sup>with</sup> if the high temperature incinerator <sup>which is put to</sup> practical use at present is used.

Burning the wastes also has problems other than production of the harmful substances. Usually, wastes contain incombustible substances such as metals and glass. Therefore, when the wastes are burnt <sup>as they</sup> are <sup>materials</sup> incombustible <sup>and</sup> ~~drugs~~ are produced and required to be removed from the incinerator, which takes much time. In terms of time and cost, it is difficult to segregate the wastes according to material <sup>type</sup> and then to process them <sup>different</sup> separately.

In addition, there are wastes, <sup>substantial amounts of</sup> most of which contain incombustible materials, such as industrial wastes and shredder dust, including <sup>the remains of</sup> pieces into which car bodies and household <sup>electric</sup> appliances are broken. Those wastes are not suitable for burning.

The other method for processing <sup>burial</sup> the wastes is to bury them. <sup>becoming increasingly</sup> [Now,] It is <sup>however</sup> difficult to secure a place where the wastes are to be buried.

In addition, there is the problem that chemical substances contained in the wastes will react <sup>when buried</sup> in the earth to resynthesize new chemical (harmful) substances. Furthermore, harmful heavy metals such as lead and/or harmful chemical substances such as dioxin contained in the wastes dissolve in rain to pollute <sup>the</sup> soil, rivers and ground water (soil pollution, <sup>and</sup> water pollution) <sup>and</sup> thereby destroy the environment <sup>greatly</sup>.

Methods appropriate (efficient and safe) <sup>for disposal</sup> to dispose of certain <sup>ones</sup> kinds of the wastes such as PCBs and/or dioxin <sup>have</sup> <sup>been</sup> not yet found, and hence those

wastes can only be stored and kept. Such wastes ~~may~~<sup>may</sup> leak out during their storage to pollute the environment and hence ~~straightaway~~<sup>further</sup> measures are required to be taken.

In order to solve the above various problems, <sup>an</sup> apparatus capable of disposing of all wastes without producing harmful substances <sup>are desired</sup> have been demanded <sup>an</sup> for example, apparatus for thermally decomposing the wastes at high temperatures without burning them. However, it is difficult to efficiently obtain high temperatures to thermally decompose all the wastes. [Thus, those apparatus have not been put to practical use at present.]

It is therefore an object of the present invention to provide ~~an~~ inexpensive thermal decomposition apparatus ~~for~~<sup>for</sup> wastes which solves the above problems and which thermally decomposes ~~almost all~~ wastes without producing harmful substances such as soot, dust, chlorine compounds such as hydrogen chloride, nitrogen compounds such as NO<sub>x</sub> and/or dioxin.

15

*center  
Funders* — SUMMARY  
[DISCLOSURE] OF THE INVENTION

In order to achieve the above object, the present invention provides a heating chamber for heating wastes, an inlet port for introducing the wastes into the heating chamber, at least one pair of electrodes provided within the heating chamber, a light emitting heater consisting of a plurality of ~~balls~~<sup>elements</sup> which contain carbon as a main ingredient, the light emitting heater <sup>being</sup> provided between the at least one pair of electrodes so as to produce an electric discharge when a voltage is applied across the at least one pair of electrodes, and an outlet port for discharging ~~out of the~~<sup>produced by the thermal decomposition of</sup> heating chamber] gases ~~into which~~ the wastes ~~are thermally decomposed~~.

In the arrangement, electric discharges occur between the plurality of ~~balls~~<sup>elements</sup>. Since the electric discharges occur at a high temperature of about

3000 °C, almost all wastes including PCBs except for metals having high melting points are thermally decomposed at such high temperatures into harmless low molecular-weight substances without producing any harmful substances such as dioxin.

5 Thus, even wastes containing incombustible <sup>materials</sup> wastes which cannot be disposed of in the general burning method can be thermally decomposed simultaneously without being separated or segregated. Even when the wastes <sup>may contain some materials</sup> which may produce dioxin in the burning process are contained, they are thermally decomposed without being segregated. Thus, much  
10 time and cost are <sup>saved in the disposal</sup> not required for disposing of the wastes.

After the thermal decomposition, few <sup>remains</sup> dregs are produced and no work for removing such <sup>remains</sup> dregs is required.

The remainder of the burned wastes containing dioxin produced by burning the wastes, and wastes such as PCBs whose processing methods  
15 have not been found and which have only been stored and kept are thermally decomposed similarly into harmless low molecular-weight substances.

As described above, the present invention is realized by generating an extremely high temperature of about 3000 °C efficiently in a stabilized  
20 manner and by maintaining <sup>this</sup> its temperature.

The electric discharging region is at a high temperature of about 3000 °C and a position distant ten-odd centimeters from the discharging region is at about 200 °C or less. Thus, the inner and outer walls of the thermal decomposition apparatus is capable of sufficiently <sup>maintaining</sup> keeping a high  
25 temperature of about 3000 °C even <sup>with</sup> they have a simple structure. Thus, such <sup>an</sup> apparatus has a simple structure and is made inexpensively.

The low molecular-weight substances produced by the thermal

decomposition are rapidly cooled from about 3000 °C to about 200 °C or less to [thereby] eliminate the probability of dioxin being reproduced. If they are cooled gradually, they <sup>materials are</sup> are placed for a long time <sup>for a sufficient</sup> at a temperature <sup>time</sup> where dioxin is likely to <sup>be</sup> produce.

5 The thermal decomposition apparatus preferably comprises ~~a~~ oxygenless state forming means for placing the heating chamber in an oxygenless <sup>free environment</sup> state such that the plurality of <sup>spheres</sup> balls are placed in an oxygenless <sup>free</sup> state. Thus, the plurality of <sup>spheres prevented from oxidation, deterioration, and deformation</sup> balls are difficult to oxidize, deteriorate, and deform <sup>life</sup> to decrease in discharge efficiency, and are usable <sup>which would result in a</sup> for a long time.

10 For example, when the plurality of ~~balls~~ <sup>spheres</sup> each take the form of a perfect sphere, they provide a very high discharging efficiency, whereas when they are deformed due to their oxidization and deterioration, the discharging efficiency <sup>free environment</sup> can decrease. The oxygenless state in the present invention implies that the oxygen concentration is lower than that in air.

15 <sup>It is preferable that the oxygen concentration be much lower than that in air.</sup> [As the oxygen concentration becomes lower, it is more preferable.

If it is lower than that in air, there is no problem.] When the oxygen concentration exceeds that in air, the plurality of ~~balls~~ <sup>spheres</sup> are liable to be oxidized and deteriorated.

The apparatus preferably comprises <sup>a</sup> decompressing means for decompressing the heating chamber such that the plurality of ~~balls~~ <sup>spheres</sup> are placed in a vacuum <sup>environment</sup> state. In this case, a high discharging efficiency and a high temperature are <sup>readily</sup> easily obtained. In addition, a high temperature is obtained with <sup>less</sup> small power to thereby reduce the operating cost of the apparatus. Like the case where the plurality of ~~balls~~ <sup>spheres</sup> are placed in the oxygenless <sup>free environment</sup> state, they are <sup>prevented from deterioration</sup> difficult to deteriorate and <sup>have a long</sup> usable for a long time <sup>life</sup>.

25 Since the density of molecules present in the vacuum <sup>production of</sup> state is low, new chemical substances are difficult to produce due to recombination of

decomposed molecules, advantageously. The vacuum [state] in the present invention implies that the <sup>pressure</sup> vacuum degree is less than the atmospheric pressure.

*It is preferable to have a lower pressure, or higher vacuum.*  
 [As the vacuum degree becomes higher, it is more preferable.] A  
 5 medium vacuum ( $10^{-2}$  <sup>Pa to</sup> or more and less than <sup>to</sup>  $10^4$  Pa) will suffice. It may be a lower vacuum ( $10^4$  <sup>to</sup> or more and less than the atmospheric pressure).

The plurality of ~~balls~~ <sup>consisting</sup> may be ~~each~~ <sup>material</sup> made of at least one selected <sup>and mixtures thereof</sup> from the group of charcoal, graphite and a carbon composite material. As an example of charcoal, Japanese Bincho charcoal can be <sup>selected</sup> named. Carbon  
 10 such as charcoal and graphite has many pores on its surface and in ~~its~~ <sup>the</sup> inside in which a gas is adsorbed. Thus, there is the problem that at high temperature the adsorbed gas will be <sup>released</sup> discharged. Thus, it is preferable to process carbon, such as charcoal and/or graphite, such that their pores are closed to prevent adsorption of a gas.

15 The plurality of ~~balls~~ <sup>plates are preferably</sup> each have impermeability preferably. In that case, their substance absorptability <sup>tion</sup> is low to thereby decrease the probability that they will adsorb or <sup>desorb</sup> release harmful substances in use. Thus, <sup>this prevents</sup> since they are difficult to deteriorate <sup>ion</sup> with oxidization <sup>or by</sup> and harmful chemical substances, <sup>and results in a long</sup> they are usable for a long time <sup>life</sup>.

20 It is preferable that the plurality of balls ~~each~~ take the form of a sphere. In order to cause electric discharges efficiently between the plurality of ~~balls~~ <sup>are</sup>, they are preferably in point contact, one with another. If they are in line or surface contact, <sup>each other</sup> one with another <sup>an</sup> many undesirable great flows of electric currents <sup>ing</sup> would occur to thereby reduce the discharge  
 25 efficiency. Thus, when ~~they are~~ <sup>are</sup> each in the form of a sphere, they are [necessarily] in point contact, <sup>others</sup> one with another, the discharges are performed efficiently, a high temperature is easily obtained, and the

operating cost of the apparatus is <sup>low</sup> reduced

The use of the plurality of ~~balls~~ <sup>adapters</sup> for a long time deteriorates <sup>the spheres from</sup> [themselves] due to the discharges and oxidization [to] thereby deform<sup>(us)</sup> them [possibly] Especially, when the electric discharges concentrate on particular <sup>area</sup> part of the ~~balls~~ <sup>spheres</sup>, the particular <sup>area is</sup> part <sup>is</sup> liable to deteriorate<sup>ion</sup> [greatly] If the plurality of balls each take the form of a sphere, they rotate due to the action of the electric discharges. Thus, the electric discharges are difficult to concentrate on the particular part and there is a high probability that the electric discharges will occur uniformly among all <sup>part</sup> areas on [of] them. Thus, even when they are deteriorated and/or deformed, they are kept in the form of a sphere, and the probability that the electric discharge efficiency will be reduced is <sup>advantageously</sup> low, <sup>advantageously</sup>

As long as the plurality of balls are placed in point contact, [one with another] they may each take the form of a polyhedron such as a dodecahedron or icosahedron. The term "sphere" used in the present invention should include a true sphere as well as a polyhedron. The plurality of balls each <sup>preferably</sup> take the form of a perfect sphere [preferably].

Pressing means for pressing the wastes against the plurality of balls may be provided within the heating chamber.

By this arrangement, the wastes are placed in efficient contact with the discharging portions of the plurality of balls. Thus, the wastes are heated efficiently at a temperature, for example, of about 3000 °C, to thereby improve the <sup>thermal</sup> <sup>tion</sup> [heat] decomposing efficiency of the wastes.

The apparatus may further comprise a filter made of at least one of active<sup>e</sup> [ate] carbon and charcoal for allowing the decomposed gases to pass [there]through.

In this case, even when the decomposed gases contain hydrocarbons,

heavy metals and/or undecomposed harmful substances, the filter will adsorb them <sup>harmful substances</sup> to prevent them from being discharged <sup>out of the apparatus</sup>

The apparatus may further comprise a vacuum meter for measuring the pressure within the heating chamber, and pressure  
5 adjusting means for adjusting the pressure within the heating chamber to a predetermined value.

In this arrangement, the inside of the heating chamber is automatically adjusted to an optimal pressure.

The apparatus may further comprise an intervening spacer which  
10 contain <sup>primary</sup> carbon as a <sup>main</sup> ingredient, the intervening spacer being placed between the plurality of ~~balls~~ <sup>balls</sup> and an inner wall of the heating chamber. Since, in this arrangement, the inner wall of the heating chamber is not contact with the plurality of <sup>balls</sup> ~~balls~~ of high temperatures, the former is <sup>prevented from deterioration</sup> ~~difficult to deteriorate~~ with heat to thereby improve the durability of the  
15 inner wall.

The intervening spacer may be made of a carbon material such as <sup>be</sup> impermeability graphite, and its shape is not <sup>Especially</sup> limited and may take the form of a plate or rod.

At least portions of the inner wall of the heating chamber which are  
20 placed in contact with the plurality of balls may be made of a monolithic refractory which contains at least one <sup>material</sup> selected from the group <sup>consisting</sup> of boron nitride (BN), niobium (Nb), silicon carbide (SiC), boron carbide ( $B_xC_y$ ), magnesium oxide (MgO), hafnium oxide (HfO), hafnium dioxide (HfO<sub>2</sub>), and beryllium aluminum oxide ( $Al_2BeO_4$ ,  $BeO \cdot Al_2O_3$ ). In this  
25 arrangement, the monolithic refractory has high thermal resistance which <sup>withstands</sup> ~~resists~~ a high temperature of about 3000 °C. Thus, the inner wall of the heating chamber <sup>maintains its integrity</sup> ~~is rarely deteriorated~~.

Especially, since ~~the~~ boron nitride has a high melting point of 3000 °C, the monolithic refractory containing this material is excellent in thermal resistance, and the inner wall of the heating chamber <sup>maintains its integrity and does not melt,</sup> is rarely deteriorated or melted due to heat. The inner wall of the heating chamber has high electric <sup>insulation</sup> resistance at high temperature, and no electric current flows through points where the inner wall of the heating chamber is in contact with the plurality of ~~balls~~ <sup>balls</sup>.

Addition of niobium and/or silicon carbide to the monolithic refractory improves its strength at high temperatures. Boron carbide includes various compounds of two ingredients. Monolithic refractories containing such compound have a low density and a higher strength. Monolithic refractories containing hafnium oxide exhibit excellent corrosion resistance. Monolithic refractories containing magnesium oxide exhibit excellent <sup>thermal</sup> ~~heat~~ and fire resistance.

At least a part of the at least one pair of electrodes may take the form of a rod or horn surrounded by the plurality of balls to thereby improve the discharge efficiency.

The apparatus may further comprise a pipe for introducing liquid wastes into the heating chamber.

The thermal decomposition apparatus may further comprise a decomposed gas harm eliminating device for thermally decomposing harmful materials remaining in the decomposed gases into harmless gases. The decomposed gas harm eliminating device may comprise: a decomposed gas heating chamber for heating the decomposed gases; a decomposed gas inlet port for introducing the decomposed gases into a decomposed gas heating chamber; at least one pair of second electrodes provided within the decomposed gas heating chamber; a second light emitting heater consisting

of a plurality of second balls which contain carbon as a <sup>primary</sup> ~~main~~ ingredient, the second light emitting heater being provided between the at least one pair of second electrodes so as to produce an electric discharge when a voltage is applied across the at least one pair of second electrodes; a

5 harmless gas outlet port for discharging ~~out of~~ the ~~decomposed gas heating chamber~~ harmless gases ~~to~~ which the decomposed gases are changed; and a filter comprising at least one of active carbon and charcoal for allowing the harmless gases to pass ~~ther~~ through.

In such arrangement, electric discharges occur between the

10 plurality of second balls of the device. The discharging regions are at a high temperature of about 3000 °C. Thus, even when the decomposed gases contain hydrocarbon compounds and/or harmful substances, the device thermally decomposes them completely to <sup>render</sup> ~~make~~ them harmless. Thus, there is <sup>a very low</sup> ~~substantially no~~ probability that ~~the~~ <sup>any</sup> harmful substances will

15 be discharged <sup>from</sup> ~~out of~~ the apparatus.

The decomposed gas harm eliminating device may further comprises at least one of: a second vacuum meter for measuring the pressure within the decomposed gas heating chamber, and second pressure adjusting means for adjusting the pressure within the decomposed gas

20 heating chamber to a predetermined value; a second intervening spacer which contain carbon as a <sup>primary</sup> ~~main~~ ingredient, the spacer being placed ~~at least~~ between the plurality of second balls and an inner wall of the decomposed gas heating chamber; at least portions of the inner wall of the decomposed gas heating chamber which are placed in contact with the plurality of

25 second balls <sup>the inner wall</sup> being made of a monolithic refractory which contains ~~at least one~~ <sup>material</sup> selected from the group <sup>consisting</sup> of boron nitride, niobium, silicon carbide, boron carbide, magnesium oxide, hafnium oxide, hafnium dioxide, ~~and~~ beryllium

aluminum oxide; <sup>and mixtures thereof</sup> and a second pair of electrodes having at least a part thereof in the form of a rod or horn surrounded by the plurality of second balls.

# DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS — center & underline [BEST MODE FOR CARRYING OUT THE INVENTION]

Embodiments of the thermal decomposition furnace according to the present invention will be described in more detail with reference to the accompanying drawings. The terms indicating directions such as "up", "down", "front", "rear", "right" and "left" represent respective directions in each of the drawings for convenience of explanation.

It is to be noted that the present invention is not limited to the embodiments described below.

25

(First Embodiment)

[FIG. 1 is a perspective view of a thermal decomposition apparatus

FIG. 14b shows a horizontal cross-sectional view of a lower portion of a heating chamber of a thermal decomposition apparatus for wastes as a sixth embodiment;

FIG. 17b shows a plan view of the mount to which intervening spacers are fixed and

for wastes as the first embodiment. FIG. 2 is a cross-sectional view taken along a line A-A of FIG. 1. FIG. 3 is a cross-sectional view taken along a line B-B of FIG. 1.]

The apparatus 1 includes an internal heating chamber 10 with an inlet port 20 on its front (on the left side thereof in FIG. 3) through which the wastes are introduced into the heating chamber 10 and an outlet port 21 on its rear (on the right side thereof in FIG. 3) through which the resulting thermally decomposed wastes are discharged from the heating chamber 10. The inlet port 20 has an operable door 22 such that when closed, <sup>provides an seal</sup> the airtightness of the heating chamber 10 <sup>is maintained</sup>.

The thermal decomposition apparatus 1 has an outer wall 11 of a 4-layered structure composed of an innermost refractory concrete layer 13a, an inner iron plate 12a, an outer refractory concrete layer 13b, and an outermost iron plate 12b coated with a heat resisting <sup>ant</sup> coating. A portion of the innermost refractory concrete layer 13a positioned under a plurality of balls 40, in the form of <sup>ant</sup> a sphere, is replaced with a heat-resisting firebrick layer 14 whose joints are filled with a monolithic refractory, such as refractory concrete (not shown), to improve the airtightness of the heating chamber 10.

The inside of the heating chamber 10 is heated to a high temperature of about 3000 °C, as will be described later. However, a temperature at a position <sup>and the distance on the order of scores of centimeters</sup> distant from scores of centimeters from <sup>the</sup> the plurality of balls 40 is at a temperature of not higher than 200 °C, and the inside of the heating chamber 10 is in an oxygen <sup>free</sup> less or vacuum state. Thus, heat conduction is <sup>minimal</sup> hardly performed and <sup>such</sup> a simple structure will suffice for the outer wall 11.

The rectangular parallelepiped space surrounded by a refractory

concrete layer 13a forms the airtight heating chamber 10 where the wastes introduced through the inlet port 20 are heated and thermally decomposed, and the resulting gases are discharged from the outlet port 21.

The heating chamber 10 is filled in its lower portion with a plurality of balls 40 <sup>comprised primarily</sup> of carbon such as graphite. A light emitting heater 41 consists of a plurality of balls 40. Since the plurality of balls 40 each takes the form of a sphere, adjacent ones ~~[of them]~~ are in point contact with each other. The composition of the balls 40 and a method of making them will be described in detail later.

A pair of plate-like carbon electrodes 30 are each disposed on ~~a~~ <sup>of</sup> respective ~~one of~~ opposite sides <sup>of</sup> a lower portion of the heating chamber 10 such that the plurality of balls 40 are disposed between the pair of carbon electrodes 30 from which a corresponding pair of carbon rods 31 ~~[outward]~~ <sup>outwardly</sup> extend ~~[respectively]~~ through the corresponding outer walls 11 of the apparatus 1. Each carbon rods 31 may be replaced with a heat-resisting <sup>ant</sup> refractory stainless steel one. It is to be noted that when the apparatus 1 has a structure in which the pair of stainless steel rods extend through the ~~[corresponding pair of]~~ <sup>and</sup> carbon electrodes 30 ~~[to]~~ come into contact with the plurality of balls 40, the portions of the pair of stainless steel rods which comes ~~into~~ into contact with the plurality of balls 40 should be covered by a carbon material to prevent deterioration thereof.

The outlet port 21 <sup>is in</sup> fluid communication <sup>ion</sup> with a vacuum pump 51 through an exhaust pipe 23. The vacuum pump 51 corresponds to <sup>or</sup> means for producing an oxygen <sup>free</sup> ~~less~~ <sup>environment</sup> state, or decompressing means as an element of the present invention. A vacuum meter and pressure adjusting means (not shown) are provided within the exhaust pipe 23. The pressure within the heating chamber 10 is measured by the vacuum meter. When the

pressure measured by the vacuum meter exceeds a predetermined value,  
 [an] excess gas is automatically adjusted (discharged) by the pressure  
 adjusting means to [thereby] maintain the pressure within the heating  
 chamber 10 at a constant value. In order that the heating chamber 10 is  
 5 placed <sup>in</sup> ~~at~~ the oxygen <sup>free</sup> ~~less~~ or vacuum <sup>environment</sup> ~~state~~, any means may be used as the  
 oxygen <sup>free environment</sup> ~~less state~~ producing means or decompressing means.

A fiber-like active carbon filter 50 is provided within the exhaust  
 pipe 23. The active carbon <sup>filter is a porous matrix comprising micropores with diameters</sup> ~~has~~ on its surface innumerable open pores <sup>less than 20 nm, medium</sup>  
 which include micro ones having a diameter of not more than 2 nm, <sup>pores with diameters</sup>  
 10 medium ones having a diameter of more than 2 nm and less than 100 nm, <sup>from 20 nm to 100 nm,</sup>  
 and macro ones having a diameter of not less than 100 nm <sup>and macropores</sup> ~~and has a~~ <sup>having diameters</sup>  
 specific surface area of 500-1700 m<sup>2</sup>/g. Thus, the active carbon has a  
 strong <sup>and</sup> ~~absorptivity~~ <sup>can physically</sup> ~~to selectively~~ adsorb relatively large molecules  
<sup>physically</sup>, wherein the pores of various sizes adsorb various molecules.  
 15 Especially, the active carbon is excellent in <sup>and</sup> ~~adsorbing~~ hydrocarbon<sup>s</sup> such as  
 methane. Instead of the fiber-like active carbon filter 50, particulate  
 active carbon may be used as the filter. A filter of a material other than  
 carbon may be used as long as it has excellent <sup>adsorptivity</sup> ~~adsorbability~~.

A pair of openings 52 each are provided axially outside a respective  
 20 ~~one of the~~ pair of carbon electrodes 30 through <sup>the</sup> ~~a~~ corresponding ~~one of the~~  
 opposite <sup>for</sup> ~~sides of the apparatus 1~~ ~~so that~~ inspection/maintenance of the  
 inside of the apparatus 1 (including inspection of <sup>very</sup> ~~a~~ deterioration in the  
 quality, <sup>and replacement thereof</sup> ~~and replacement~~) of the balls 40 and carbon electrodes 30).

Each opening 52 is covered with an ceramic plate 53, which is  
 25 removably fixed by <sup>b</sup> ~~bolts~~ 54 to the outer wall 11. A refractory sealing  
 sheet (not shown) is provided between each cover 53 and a corresponding  
 [one of opposite] surfaces ~~of~~ of the iron plate 12b of the outer wall 11 to provide

satisfactory~~[inside]~~ airtightness for the apparatus 1. A refractory concrete block 55 is filled between each carbon electrode 30 and a corresponding cover 53 to provide satisfactory maintenance of the temperature within the apparatus 1. The cover 53 may be an iron plate covered with an  
 5 insulating material. The refractory concrete block 55 may be replaced with a firebrick.

The four members, i.e., the cover 53, refractory concrete block 55, carbon electrode 30 and carbon rod 31, form an united electrode unit 57. Thus, the cover 53, refractory concrete block 55, carbon electrode 30 and  
 10 carbon rod 31 are not required to be removed individually to replace the carbon electrode 30 with a new one. Instead, the electrode unit 57 is ~~only~~ required to ~~be~~ replaced wholly ~~[with another one]~~ to ~~[thereby]~~ facilitate replacing the carbon electrode 30 with a corresponding new <sup>electrode</sup> ~~one~~.

An outer rectangular iron frame 56 is provided so as to fit fixedly  
 15 into an inner edge of each opening 52. A corresponding inner rectangular iron frame 59 is received within the corresponding rectangular iron cylindrical frame 56 so as to fit fixedly over a corresponding end portion of the refractory concrete block 13 for covering purposes such that the iron frame 59 slides along with the electrode unit 57 relative to the frame 56 to  
 20 move the electrode unit 57 into/out of the opening 52.

A method of thermally decomposing the wastes, using such decomposing apparatus 1, will be described in detail next.

First, the door 22 of the inlet port 20 for the decomposition apparatus is opened, the wastes (not shown) are cast into the apparatus so  
 25 as to be placed on the plurality of balls 40.

The vacuum pump 51 is then actuated to evacuate the heating chamber 10 into a vacuum state (for example, a high vacuum of about  $6.7 \times$

$10^{-2}$  Pa or a lower vacuum of about 0.02-0.06 MPa). Thus, the plurality of balls 40 ~~filled into~~ the heating chamber 10 are also placed in the vacuum state.

The pair of carbon rods 31 are connected to a power supply (not shown). When the pair of carbon electrodes 30 are ~~impressed~~ <sup>discharged</sup> with a voltage of about 200 V (a current of 300-400 A), electric discharges occur among the balls 40 within the chamber 10. Electric discharges occur in the whole of the light emitting heater 41. In order to increase the discharge power, the pair of carbon electrodes 30 are required to be supplied with a voltage of 400-500 V (a current of 100-150 A)

The mechanism of occurrence of the electric discharges will be described with reference to FIG. 4. <sup>a+b</sup> FIG. 4 (a) shows three balls 40 placed in contact with each other. <sup>xy</sup> FIG. 4(b) illustrates the contacting portions of any two of the balls 40 in an enlarged view.

Since the plurality of balls 40 <sup>are in the shape</sup> each take the form of a sphere, ~~any~~ adjacent ones ~~thereof~~ are in point contact with each other. Each ball 40 has a rugged surface microscopically. Thus, any adjacent balls 40 have microscopical convexities in contact with each other and concavities between the convexities on this surfaces. When a voltage is applied across the pair of electrodes, electric currents flow through points at which any two balls 40 are in contact with each other. However, the ~~areas~~ of the contact points are small and large currents cannot flow through the contact points, and electric discharges 42 occur across the concavities on the surfaces of the adjacent balls. When the balls 40 are in line/surface contact with each other ~~to thereby~~ <sup>ins</sup> provide large contact areas, large currents would flow through the areas and the discharge efficiency is reduced.

The discharge region (at spark 42) is at a temperature of about 3000 °C and the environment of the plurality of balls 40 is stabilized at a high temperature of 3000 °C in a <sup>relatively</sup> short time <sup>on the order</sup> of scores of seconds after a voltage is applied across the pair of carbon electrodes. At this time, the

5 outer wall 11 (iron plate 12b) of the decomposition apparatus 1 is at about room temperature. If the electric discharges occur in a stabilized state, <sup>can be reduced to</sup> the [low] voltage ~~of~~ about 30 V (a current of 300-400 A) <sup>desired</sup> [will suffice for the voltage to be applied]. The resulting temperature may be adjustable depending on the applied voltage, as <sup>desired</sup> requested.

10 The use of the plurality of balls 40 for a long time <sup>causes deterioration. This is due to the electrical discharge resulting in oxidation and subsequent deformation. This is especially true when the discharges are concentrated in a limited area of a sphere.</sup> [deteriorates] [themselves due to the discharges and oxidization to thereby deform them possibly] [Especially, when the electric discharges concentrate on particular parts of the balls 40, the balls 40 are liable to deteriorate greatly]. Since the plurality of balls 40 each take the form of a sphere, they rotate

15 due to the action of the electric discharges. Thus, the electric discharges are difficult to concentrate on the particular parts of the balls 40 and there is a high probability that the electric discharges will occur uniformly <sup>over the entire sphere</sup> among whole of them. Thus, even when they are deteriorated and/or deformed, they <sup>maintain the shape</sup> are kept in the form of a sphere, and the probability that

20 the electric discharge efficiency will be reduced is <sup>low</sup> advantageously.

The wastes placed on the plurality of balls 40 are not burnt <sup>and</sup> but are heated to a high temperature of about 3000 °C <sup>to be</sup> thermally decomposed into harmless gases of low molecular <sup>weight</sup> substances without producing harmful substances such as soot <sup>and</sup> dust, chlorine compounds such as

25 hydrogen chloride, nitrogen compounds such as NO<sub>x</sub>, and harmful substances such as dioxin. If such harmful substances are contained in the wastes, they are similarly decomposed thermally at the high

temperature into gases of harmless low molecular<sup>weight</sup> substances.

Almost all wastes including powder/solid PCB<sub>s</sub> except for metals having high boiling points are thermally decomposed at the high temperature of about 3000 °C. In <sup>which</sup> ~~that~~ case, few <sup>solids</sup> ~~regs~~ remain. Thus, 5 incombustible wastes including glass articles such as bottles and metal articles such as cans, industrial wastes, medical wastes and shredder dust are thermally decomposed simultaneously without being segregated, not to mention general wastes such as kitchen garbage and resins. When glass articles such as bottles are broken into pieces of substantially the same size 10 as the balls 40, they come easily into contact with the balls 40 to thereby improve the thermal decomposition speed. Formless wastes are temporarily hardened to a lump having a fixed shape, for example, by compression and then broken into pieces to thereby improve the thermal decomposition speed similarly.

15 The electric discharges produce heat and light. The light is considered to be effective in <sup>enhancing</sup> ~~expediting~~ the thermal decomposition of the harmful substances. Especially, when dioxin is thermally decomposed, the <sup>enhancement</sup> ~~effect~~ of this thermal decomposition is considered to be <sup>high</sup> ~~large~~.

The decomposed gases can contain harmless low molecular weight 20 substances as well as hydrocarbon<sup>s</sup> and heavy metals, and are adsorbed by the active carbon filter 50. Thus, they are not discharged from the outlet port 21 of the apparatus 1. <sup>Any</sup> A very small amount of harmful substances <sup>are</sup> ~~can~~ remain, but <sup>is</sup> adsorbed by the filter 50. Thus, no <sup>harmful</sup> ~~such~~ gas is discharged from the outlet port 21 of the apparatus 1.

25 The filter 50 <sup>can be regenerated by spraying</sup> is restored repeatedly with water vapor of 120-200 °C

(sprayed thereagainst) for reuse. Thus, this filter is excellent both in economy and prevention of secondary pollution. <sup>When the filter 50 reaches a designated loading of heavy metals, the filter 50 is replaced. The heavy metals may be recovered by methods such as grinding and sifting according to the specific gravity.</sup>

heavy metals adsorbed by the filter 50 increases, the heavy metals and other materials can be removed from the filter 50, crushed to pieces with an industrial mill and sifted according to specific gravity to collect the heavy metals.]

5 As long as the object of the present invention is achieved, the positions of the inlet port 20, outlet port 21, vacuum pump 51 and the pressure adjusting device relative to the apparatus 1 are not limited to those of the present embodiment. For example, while the vacuum pump 51 is illustrated as being <sup>disposed</sup> provided outside the apparatus 1 in the present  
10 embodiment, it may be <sup>disposed</sup> provided within the apparatus 1.

While in the present embodiment the wastes are illustrated as being thermally decomposed in a state where they are placed on the plurality of balls 40, it is preferable that ~~when~~ the wastes are pressed against the plurality of balls 40, for example, by a spring or a weight placed  
15 on the wastes, <sup>and the</sup> a percentage of the wastes coming into contact with the plurality of balls 40 increases to thereby increase the <sup>rate of</sup> thermal decomposition ~~Speed~~ of the wastes.

FIGS. 5 and 6 show a modification of the first embodiment which comprises <sup>a</sup> pressing means for pressing the wastes against the plurality of  
20 balls 40. FIG. 5 is a vertical cross-sectional view of the thermal decomposition apparatus 1a of the modification. FIG. 6 is a horizontal cross-sectional view of the thermal decomposition apparatus 1a. In FIGS. 5 and 6, the same reference numeral as that used in FIGS. 1-4 is used to denote the same element as, or an element corresponding to, that of the  
25 thermal decomposition apparatus 1 of the first embodiment.

Further description of elements of the thermal decomposition apparatus 1a of the modification, identical or corresponding to ones of the

thermal decomposition apparatus 1 of the first embodiment will be omitted and only elements of the modification different from those of the thermal decomposition apparatus 1 of the first embodiment will be explained next.

5 A pressure plate 61 ~~which~~ presses the wastes 60 against the plurality of balls 40 due to its own weight <sup>and</sup> is suspended in a horizontal state by a rope 62 within the heating chamber 10. The rope 62 separates halfway into four subrope portions fixed to the respective corners of the pressure plate 61 such that the pressure plate 61 can <sup>be</sup> easily <sup>maintained in</sup> take a horizontal attitude.

10 The rope 62 is connected at an upper end to an elevator 64 attached to the top of the thermal decomposition apparatus 1a such that the elevator 64 feeds out or rewinds the rope 62 to elevate and lower the pressure plate 61 within the heating chamber 10.

The heating chamber 10 has a pair of grooves 66 each provided on a  
15 respective one of opposite inner walls thereof and receiving slidably a respective ~~one of a pair of~~ horizontal projections ~~68~~ each provided at a respective one of opposite sides of the pressure plate 61 such that the pressure plate 61 move up and down along the pair of grooves 66 in the opposite inner walls in a stabilized manner.

20 ~~By~~ The pressing means which comprises <sup>a</sup> ~~such~~ pressure plate 61, rope 62 and elevator 64. The pressure plate 61 is lowered depending on a degree of decomposition of the wastes 60 (a decomposed size of the wastes 60). Thus, the wastes 60 can be pressed against the plurality of balls 40 to  
25 maintain an efficient contact state at all times to thereby improve the decomposing <sup>tion</sup> speed of the wastes 60. <sup>The decomposition speed</sup> ~~which~~ can be improved by about 30-40 % depending on the weight of the pressure plate 61, the kind of wastes 60 and the degree of vacuum.

Although the rope 62 is connected to the elevator 64 through the outer wall 11 of the decomposition apparatus 1a, the airtightness of the heating chamber 10 is sufficiently maintained.

The material of the pressure plate 61 is not limited as long as it has a sufficient weight, heat resistance and corrosion resistance. The material of the rope 62 is not [especially] limited as long as it has sufficient strength, heat resistance and corrosion resistance. The materials of the pressure plate 61 and rope 62 preferably include carbon, impermeability<sup>to</sup> graphite, ceramic or heat-resisting stainless steel. The elevator 64 may be of the electrically or manually actuated type.

[While in the modification the pressing means which presses the wastes 60 against the plurality of balls 40 with the weight of the pressure plate 61 is employed, pressing means may be employed which presses the wastes 60 against the plurality of balls 40 with a spring.]

*As an alternative, the means for pressing the pressure plate 61 against the wastes 60 may include a spring.*

15

(Second Embodiment)

FIG. 7 is a vertical cross-sectional view of a thermal decomposition apparatus 2 for wastes in the second embodiment. FIG. 8 is a horizontal cross-sectional view taken along a line C-C in FIG. 7. The same reference numeral is used to denote the identical or similar elements of the second and first embodiments in FIGS. 7, 8 and 1-4.

The thermal decomposition apparatus 2 of the second embodiment has an inlet port<sup>25</sup> (20) suitable for introducing liquid wastes such as waste oils, waste liquids and/or PCB<sub>3</sub> into the heating chamber, and is suitable for disposing<sup>tion</sup> of such liquid-like wastes. Further description of elements of the thermal decomposition apparatus 2 of the second embodiment identical or similar to those of the thermal decomposition apparatus 1 of the first

embodiment will be omitted and only elements of the second embodiment different from those of the first embodiment will be explained next.

An inlet pipe 24 extends into the heating chamber 10 through a side wall of the decomposition apparatus 2 for feeding the liquid wastes into the heating chamber. The inlet pipe 24 separates into a plurality of subpipes (two in FIG. 8) and then merges into a single second pipe which is terminated and fixed in the inner wall of the heating chamber 10 opposite to the side wall of the heating chamber 10 through which the inlet pipe 24 passes.

The subpipes placed within the heating chamber 10 each have a plurality of holes 26 arranged through its length on its lower surface such that the liquid wastes 28 flowing through the inlet pipe 24 are discharged in the form of a shower [as the case may be] from the plurality of holes 26 against the plurality of balls 40. The inlet port <sup>25</sup>[20] suitable for introducing liquid wastes is composed of the inlet pipe 24 and its holes 26.

The shape of portions of the inlet tube 24 within the heating chamber 10 is not especially limited, but is freely designable. While in the present embodiment the inlet pipe 24 is illustrated as being separated into the subpipes which then merge into one, it may be a non-divergent <sup>pipe</sup>one or a divergent and non-merging <sup>pipe</sup>one.

The material of the inlet pipe 24 is not especially limited as long as it has heat resistance and corrosion resistance to liquid wastes.

Preferably, the material of the inlet pipe 24 include, for example, carbon, impermeability <sup>le</sup>graphite, ceramic or heat resistance <sup>+</sup>stainless steel.

A method of thermally decomposing the liquid wastes using the thermal decomposition apparatus 2 is similar to that used in the case of the first embodiment and further description thereof will be omitted.

(Third Embodiment)

FIG. 9 is a perspective view of a thermal decomposition apparatus 3 for wastes as a third embodiment. FIG. 10 is a horizontal cross-sectional view of ~~a part of~~ a decomposed gas harm eliminating device 3b of the thermal decomposition apparatus 3.

The thermal decomposition apparatus 3 as the third embodiment comprises a thermally decomposing device 3a and a decomposed gas harm eliminating device 3b connected to the thermal decomposing device 3a.

10 The thermal decomposing device 3a thermally decomposes the wastes. The decomposed gas harm eliminating device 3b heats to a high temperature gases produced by thermal decomposition of the wastes in the thermal decomposing device 3a to thermally decompose harmful substances remaining ~~possibly~~ in the decomposed gases ~~to~~ thereby rendering

15 the decomposed gases harmless.

The thermally decomposing device 3a is identical to the thermal decomposition apparatus 1 of the first embodiment except that the former lacks a filter such as that shown by 50 and a vacuum pump such as that shown by 51 and therefore the composition of the decomposed gas harm

20 eliminating device 3b alone will be described below. In the present embodiment, the same element as, or an element corresponding to, that of the thermal decomposition apparatus 1 of the first embodiment is identified by the same reference numeral as was used in the first

*In an alternative,* embodiment. ~~(The~~ thermally decomposing device 3a may be replaced with

25 the thermal decomposition apparatus 2 of the second embodiment.

The decomposed gas harm eliminating device 3b ~~which inside~~ includes a decomposed gas heating chamber 110, has a decomposed gas

inlet port 120 on its front for introducing the decomposed gases into the heating chamber 110, and a harmless gas outlet port 121 on its rear for discharging the harmless decomposed gases out of the heating chamber 110.

The outlet port 21 of the thermally decomposing device 3a <sup>is in</sup> fluid

5 communicates <sup>on</sup> through a connecting pipe 101 with the inlet port 120 of the decomposed gas harm eliminating device 3b. A vacuum pump 15 <sup>is in</sup> fluid communicates <sup>on</sup> with the outlet port 121 through a discharge pipe 123.

The <sup>de</sup>composed gas harm eliminating device 3b has an outer wall <sup>with</sup> 111 <sup>of a</sup> 4-layered structure similar to that of thermally decomposing device 3a, <sup>the outer wall 111</sup> including <sup>as</sup> an innermost refractory concrete layer 113a, an inner iron plate 112a, an outer refractory concrete layer 113b and an outermost iron plate 112b coated with a heat resisting <sup>ant</sup> coating. A portion of the innermost refractory concrete layer 113a positioned under a plurality of second balls (to be described later) 140 is replaced with a heat-resisting refractory

10 15 firebrick layer (not shown) whose joints are filled with a monolithic refractory such as refractory concrete (not shown) to improve the airtightness of the decomposed gas heating chamber 110.

The heating chamber 110 is heated to a high temperature of about 3000 °C [as will be described later]. A temperature at a position <sup>distant</sup> [distant] <sup>on the order of</sup> scores of centimeters from the plurality of second balls 140 is not higher than 200 °C and that the heating chamber 110 is in an oxygen <sup>free</sup> less or vacuum state, so that heat conduction is <sup>minimal</sup> [hardly performed], and therefore, a [such] simple structure will suffice for the outer wall 111.

20

The heating chamber 110 for the decomposed gases comprises an airtight rectangular parallelepiped space surrounded by the innermost refractory concrete layer 113a. The innermost refractory concrete layer 113a has two groups of [through] holes 115 each [at its portion] corresponding

25

to ~~a~~ <sup>respective</sup> one of the inlet and outlet ports 120 and 121 for allowing the decomposed and harmless gases to flow ~~there~~ through into and out of the heating chamber 110, <sup>respectively</sup>

In such <sup>an</sup> arrangement, the decomposed gases introduced from the inlet port 120 are heated and decomposed within the heating chamber 110 to become harmless gases, which are then discharged from the outlet port 121 ~~to the outside~~

The decomposed gas heating chamber 110 is separated by a plurality of (6 in FIG. 10) spaced partitions 116 of a refractory firebrick into a plurality of (7 in FIG. 10) subchambers 110a-110g arranged longitudinally within the device 3b. The foremost subchamber 110a <sup>is in</sup> fluid communication <sup>on</sup> with the inlet port 120 whereas the rearmost subchamber 110g <sup>is in</sup> fluid communication <sup>on</sup> with the outlet port 121.

Each partition 116 has a plurality of ~~through~~ holes 117 provided at equal intervals through its length so as to cause adjacent subchambers to ~~be in~~ fluid communication <sup>on</sup>. In such arrangement, the decomposed gas heating chamber 110 has therein a plurality of <sup>substantially</sup> straight gas fluid paths extending through the foremost subchamber 110a, ~~through~~ holes 117, ~~through~~ subchamber 110b, ~~through~~ holes 117, ~~through~~ subchamber 110c, ~~through~~ holes 117, ~~through~~ subchamber 110d, ~~through~~ holes 117, ~~through~~ subchamber 110e, ~~through~~ holes 117, ~~through~~ subchamber 110f, ~~through~~ holes 117 and ~~the~~ rearmost subchamber 110g such that the decomposed gases entering <sup>s</sup> the inlet port 120 flows through them and discharges from the outlet port 121 to the outside.

A pair of second electrodes consisting of two plate-like carbon electrodes 130 may be each disposed on <sup>the</sup> ~~a~~ respective one of right and left sides of any of the subchambers (the second and fifth subchambers 110b and 110e from the front in FIG. 10) except for the rearmost subchamber

110g. Each carbon electrode 130 has a carbon rod 131 which extends outward through the outer wall 111 of the decomposed gas harm eliminating device 3b.

The rearmost subchamber 110g is filled with a fiber-like active carbon filter 150 and Bincho charcoal 158 to adsorb hydrocarbon<sup>s</sup> and metals. Each subchamber for which a corresponding pair of carbon electrodes 130 are disposed is filled with a plurality of second balls 140 which have the same composition as the plurality of balls 40 of the first embodiment. A second light emitting heater consists of the plurality of second balls. <sup>for an alternative,</sup> The filter 150 may be replaced with a particulate active carbon filter. A filter of a material other than carbon may be used if it has sufficient absorptivity.

The sizes and shapes of the ~~through~~ holes 115 and 117 are not <sup>except to prevent the passage of</sup> [especially] limited <sup>if</sup> the second balls 140 <sup>do not pass through the holes</sup>. If the second balls 140 each take the form of a sphere, the shape of the ~~through~~ holes 115 and 117 <sup>preferably have a cross-section</sup> ~~each take the form~~ of a triangle <sup>preferably</sup>. The ~~through~~ holes 115 and 117 ~~each~~ may take the form of a horizontal or vertical slit. For example, instead of using partitions 116 with ~~through~~ holes 117, a plurality of ceramic pillars may be arranged in parallel to form a plurality of spaced <sup>slits</sup> ~~slit-like~~ holes 117, which serve to increase the areas of openings of the ~~through~~ holes 117. Thus, use of the plurality of <sup>slits</sup> ~~slit-like~~ holes 115, 117 <sup>is processed</sup> is preferable when a large amount of decomposed gas flows through the plurality of slit-like holes.

An opening 152 is provided for each of a pair of carbon electrodes 130 in the decomposed gas harm eliminating device 3b for inspection and maintenance of the inside of the device 3b (inspection of a degree of deterioration and replacement of the plurality of second balls 140 and the

carbon electrode 130 concerned).

Each ceramic cover 153 is fixed with bolts 154 to the outer wall 111 through a refractory sheet (or seal) (not shown) <sup>covering</sup> [so as to cover] a corresponding opening 152, <sup>ing</sup> [to] thereby maintain <sup>ing</sup> [sufficiently] the inner airtightness of the decomposed gas harm eliminating device 3b. Since each refractory concrete block 155 is fitted between the corresponding carbon electrode 130 and ceramic cover 153, the temperature [maintenance] within the decomposed gas harm eliminating device 3b is sufficiently *maintained* [achieved]. *In an alternative, the* [Each] ceramic cover 153 may be replaced with an iron cover coated with an insulating material. The refractory concrete block 155 may be replaced with a refractory firebrick block.

Each ceramic cover 153, a corresponding refractory concrete block 155, a corresponding carbon electrode 130, and a corresponding carbon rod 131 compose a united electrode unit 157. [Thus, only by replacing an old or defective electrode unit 157 with a new one without replacing the ceramic cover 153, refractory concrete block 155, carbon electrode 130 and carbon rod 131 separately, the old or defective carbon electrode 130 is replaced with a new one easily.] *Thus, replacement of an old or defective electrode unit 157 is simplified.*

A rectangular iron frame 156 is provided so as to cover the inner periphery of an outer axial end portion of the corresponding opening 152 provided in the outermost refractory concrete layer 113b. A rectangular iron frame 159 is wound around [on] an outer axial end portion of the refractory concrete block 155 and also fits in the rectangular iron frame 156 such that the corresponding electrode unit 157 with the rectangular iron frame 159 is slidably moved into/out of the opening 152.

The decomposed gas harm eliminating device 3b has a plurality of inspection openings 160 provided above subchambers 110b, 110e and 110g

in FIGS. 9 and 10 and open in the upper surface thereof such that degrees of deteriorations in the second balls 140 and the refractory concrete block are inspected and/or, if necessary, the second balls 140 are replaced with another plurality of ones through the respective inspection openings.]

*The inspection openings 160 provide access for inspection and, if necessary, replacement of the second balls 140, and inspection of the refractory concrete block.*

5           The form of the decomposed gas flow paths is freely designable, for example, ~~so~~ as to be straight or zigzag, depending on the kinds and concentration of harmful substances contained in the decomposed gases and the quantities of the wastes to be decomposed. The number of subchambers filled with the second balls 140, and the quantity of second  
10 balls 140 may be adjusted appropriately. While in the present embodiment the decomposed gas flow paths are illustrated as extending horizontally, <sup>in an alternative</sup> they may extend vertically.

A plurality of decomposed gas harm eliminating devices 3b may be attached to the thermal decomposition apparatus 3a depending on the  
15 quantities of wastes to be decomposed and the quantities of decomposed gases to be produced. Thus, this <sup>invention can be applied</sup> applies to facilities which treat of a large amount of wastes.

A method of thermally decomposing wastes, using the thermal decomposition apparatus 3, will be described next. The door 22 of the  
20 thermal decomposition device 3a of the thermal decomposition apparatus 3 is opened, and the wastes are then input into the heating chamber 10 so as to placed over the plurality of balls 40. The vacuum pump 151 is then activated to evacuate the heating chamber 10 of the thermal decomposition device 3a and the decomposed gas heating chamber 110 of the decomposed  
25 gas harm eliminating device 3b to bring about a vacuum <sup>environment</sup> state (for example, of either a high vacuum of about  $6.7 \times 10^{-2}$  Pa or a lower vacuum of about 0.02-0.06 MPa). Thus, the plurality of balls 40 within the heating

chamber 10 and the plurality of second balls 140 within the decomposed gas heating chamber 110 are also placed in the vacuum <sup>environment</sup> state.

A required voltage is then applied across each pair of carbon electrodes 30 and each pair of carbon electrodes 130 to cause electric discharges <sup>among</sup> ~~between~~ the plurality of balls 40 and <sup>among</sup> ~~between~~ the plurality of second balls 140, respectively. The plurality of pairs of carbon electrodes are connected in series with a power supply (not shown). <sup>In an alternative, the electrodes</sup> ~~Although they~~ may be connected in parallel with the power supply, <sup>however</sup> ~~the~~ series connection of the plurality of pairs of carbon electrodes desirably brings about a higher discharge efficiency and a higher temperature.

Since the discharge regions are at a high temperature of about 3000 °C, the wastes are thermally decomposed into gases as in the first embodiment. The decomposed gases are discharged from the outlet port 21 and fed through the connecting pipe 101 <sup>to</sup> ~~from~~ the inlet port 120 into the decomposed gas heating chamber 110 of the decomposed gas harm eliminating device 3b.

The introduced decomposed gases come into contact with the electric discharges (sparks) occurring between the plurality of second balls 140 to be heated to a high temperature of about 3000 °C. Thus, when hydrocarbon compounds, carbon dioxide and harmful substances such as dioxin are contained in the decomposed gases, they are thermally decomposed into harmless gases, which may contain remaining hydrocarbon compounds and/or the harmful substances or metals. However, these substances are adsorbed by the filter 150 or Bincho charcoal filter 158 and hardly discharged out of the thermal decomposition apparatus 3 to the outside.

The decomposed gas harm eliminating device 3b may comprise at

least one of (a) a second vacuum meter (not shown) for measuring the pressure within the decomposed gas heating chamber 110 and second pressure adjusting means (not shown) for adjusting to a predetermined value the pressure within the decomposed gas heating chamber 110 based on a measured value of the second vacuum meter; (b) second intervening spacer which contain<sup>3</sup> carbon as a <sup>primary</sup> main ingredient (not shown) provided between the plurality of second balls 140 and at least portions of the inner wall of the decomposed gas heating chamber 110 with which the plurality of second balls 140 would otherwise contact; (c) portions of the inner wall of the decomposed gas heating chamber 110 with which the plurality of second balls 140 contact, and being composed of a monolithic refractory containing at least one selected from the group of boron nitride, niobium, silicon carbide, boron carbide, magnesium oxide, hafnium oxide, hafnium dioxide, and beryllium aluminum oxide; and (d) pairs of second electrodes at least part of which takes the form of a rod or horn (not shown) surrounded by the plurality of second balls 140.

#### (Fourth Embodiment)

FIG. 11 is a vertical cross-sectional view of a thermal decomposition apparatus 4 for wastes as a fourth embodiment as viewed from its front.

FIG. 12 is a horizontal cross-sectional view taken along a line D-D of FIG.

11. The same reference numeral is used to denote identical or similar elements of the thermal decomposition apparatus <sup>1, 3</sup>4, <sup>4</sup>4' and <sup>3</sup>4'' of the first, third and fourth embodiments.

The thermal decomposition apparatus 4 of the fourth embodiment comprises the thermal decomposition device 3a and the decomposed gas harm eliminating device 3b of the third embodiment combined as a unit

and is similar in composition to the thermal decomposition apparatus 1 of the first embodiment except that the thermal decomposition apparatus 4 takes the form of a rectangular parallelepiped (the thermal decomposition apparatus 1 of the first embodiment takes the form of two <sup>stacked one upon the other</sup> [piled] rectangular parallelepipeds) and that the heating chamber 10 has a different internal composition. Thus, further description of the identical composition will be omitted and only their different structural portions will be described next.

Provided on top of the heating chamber 10 is a decomposed gas heating chamber 110 partitioned by horizontal and vertical partitions 16 and 18 of a heat-resisting firebrick. The vertical partition 18 has a plurality of [through] holes 118 as inlet ports for the decomposed gas. A portion of the innermost refractory concrete layer 13a facing the outlet port 21 has a plurality of [through] holes 115 which places in fluid communication the heating chamber 110 and the outlet port 21 also functioning as an outlet port for harmless gases.

In such arrangement, the decomposed gases produced from the wastes by thermal decomposition are introduced from the heating chamber 10 through the [through] holes 118 into the heating chamber 110, and then through the [through] holes 115 <sup>to</sup> ~~from~~ <sup>and</sup> the outlet port 21 <sub>to</sub> the outside of the thermal decomposition apparatus 4.

The sizes and shapes of the [through] holes 115 and 118 are not especially limited if the plurality of second balls 140 do <sup>not</sup> pass through those holes. If the second balls 140 each take <sup>the</sup> form of a sphere, the shape of the <sup>cross-section of the</sup> [through] holes 115 and 118 each <sup>preferably</sup> take the form of a triangle [preferably]. The [through] holes 115 and 118 each may take the form of a horizontal or vertical slit. For example, instead of using partitions 18

with ~~through~~ holes 118, a plurality of ceramic pillars may be arranged in parallel to form a plurality of spaced slit-like holes 118, which serve to increase the opening areas of the ~~through~~ holes 115 and 118. Thus, use of the plurality of slit-like holes 115 and 118 is preferable when a large  
 5 amount of decomposed gas flows through the holes.

The heating chamber 110 is filled with the plurality of second balls 140 each in the <sup>shape</sup> ~~form~~ of a sphere. Thus, they are in point contact one with another. A second light emitting heater <sup>includes</sup> ~~consists of~~ the plurality of second balls 140.

10 A pair of second electrodes consisting of two plate-like carbon electrodes 130 are each disposed on ~~a~~ respective one ~~of~~ both ends of the decomposed gas heating chamber 110 (provided in an upper portion of the heating chamber 10) filled with the second balls 140. Each carbon electrode 130 has a carbon rod 131 attached thereto extending axially  
 15 outward through the corresponding outer wall 11 of the decomposition apparatus 4. The carbon rod 131 may be replaced with a heat <sup>ant</sup> ~~resisting~~ refractory stainless steel rod. It is to be noted that if a stainless steel rod extends through the corresponding carbon electrode 130 so as to be in contact with the second balls 140, the portion of the stainless steel rod in  
 20 contact with the second balls 140 should be covered with a carbon material so as to prevent its deterioration.

An opening 152, similar to the opening 52 provided for each of the pair of carbon electrodes 30 is provided for each of a pair of carbon electrodes 130 in the decomposition apparatus 4 for inspection and  
 25 maintenance of the inside of the heating chamber 110 (inspection of <sup>any</sup> ~~degrees of~~ deterioration <sup>and replacement thereof</sup> ~~and replacement~~ of the second balls 140 and the carbon electrode 130 ~~concerned~~).

Each ceramic cover 153 is fixed with bolts 154 to the outer wall 11 through a refractory sheet (or seal) (not shown) so as to cover a corresponding opening 152 to thereby maintain sufficiently the inner airtightness of the decomposition apparatus 4. Since each refractory concrete block 155 is fitted between the corresponding carbon electrode 130 and the ceramic cover 153, the temperature <sup>[maintenance]</sup> within the decomposition apparatus 4 is sufficiently <sup>maintained</sup> achieved. Each ceramic cover 153 may be replaced with an iron cover coated with an insulating material. The refractory concrete block 155 may be replaced with a refractory firebrick block.

Each ceramic cover 153, a corresponding refractory concrete block 155, a corresponding carbon electrode 130, and a corresponding carbon rod 131 compose a united electrode unit 157. [Thus, only by replacing an old or defective electrode unit 157 with a new one without replacing the ceramic cover 153, refractory concrete block 155, carbon electrode 130 and carbon rod 131 separately, the old or defective carbon electrode 130 is replaced with a new one easily.]

*Thus, replacement of an old or defective electrode unit 157 is simplified.*

A rectangular iron frame 156 is provided so as to fit fixedly into an edge of the corresponding opening 152 at its edge to thereby cover a corresponding portion of the refractory concrete layer 13b. A rectangular iron frame 159 fits fixedly over an outer axial end portion of the refractory concrete block 155 and also fits in the rectangular iron frame 156 such that the corresponding electrode unit 157 with the rectangular iron frame 159 is slidably moved into/out of the opening 152.

The decomposition apparatus 4 has an inspection opening 160 provided above the heating chamber 110 and open in the upper surface.

[thereof such that degrees of deteriorations in the second balls 140 and the

*The inspection opening 160 provides access for inspection and, if necessary, replacement of the second balls 140, and inspection of the refractory concrete block.*

[refractory concrete block are inspected and/or that, if necessary, the second balls 140 are replaced with another plurality of ones through the respective inspection openings.]

The composition of the heating chamber 110 and the quantity of the second balls 140 may be adjusted depending on the kinds and concentrations of harmful substances contained in the decomposed gases and the quantity of wastes to be decomposed.

A portion of the thermal decomposition apparatus 4 corresponding to the decomposed gas harm eliminating device 3b may comprise at least one of the same elements (a)-(d) as were described above with respect to the decomposed gas harm eliminating device 3b of the third embodiment.

A method of thermally decomposing the wastes, using the thermal decomposition apparatus 4, will be described next. The door 22 of the thermal decomposition apparatus 4 is opened, and the wastes are then cast into the heating chamber 10 so as to placed over the plurality of balls 40.

The vacuum pump 51 is then activated to evacuate the thermal decomposition apparatus 4 to bring about a vacuum <sup>environment</sup> [state] (for example, of either a high vacuum of about  $6.7 \times 10^{-2}$  Pa or a lower vacuum of about 0.02-0.06 MPa). Thus, the plurality of balls 40 within the heating chamber 10 and the plurality of second balls 140 within the decomposed gas heating chamber 110 are also placed in the vacuum <sup>environment</sup> [state].

A required voltage is applied cross each of the first and second pairs of carbon electrodes 30 and 130 to cause electric discharges <sup>among</sup> [between] the plurality of first balls 40 and <sup>among</sup> [between] the plurality of second balls 140. [Since] the respective discharge regions are at a high temperature of about 3000 °C and hence the wastes are thermally decomposed into gases as in the first embodiment and introduced through the respective groups of

[through]holes 118 into the decomposed gas heating chamber 110. [Since]  
 The discharge regions occurring between the plurality of second balls 140  
 are also at a high temperature of about 3000 °C<sup>and</sup>, the decomposed gases in  
 contact with the discharge regions are also heated to about 3000 °C. Thus,  
 5 even when hydrocarbon compounds, carbon <sup>monoxide</sup> ~~dioxide~~ and harmful  
 substances such as dioxin remain in the decomposed gases, they are  
 thermally decomposed into harmless gases. Furthermore, the harmless  
 gases pass through the [through]holes 115<sup>to</sup> ~~and~~ the filter 50. Thus, even  
 when hydrocarbon compounds and harmful substances still remain in the  
 10 harmless gases, or even when the harmless gas contains metals, they are  
 adsorbed by the filter 50 without being [almost] discharged out of the  
 thermal decomposition apparatus 4, <sup>leaving</sup> ~~and~~ only harmless low  
 molecular-weight substances ~~are~~ discharged out of the apparatus 4.

A small compact thermal decomposition apparatus for wastes in  
 15 which the thermal decomposing device and the decomposed gas harm  
 eliminating device are combined as a unit is greatly suitable for use in  
 small-scaled facilities which discharge a small amount of general wastes.

#### (Fifth Embodiment)

20 FIG. 13 is a vertical cross-sectional view of a thermal decomposition  
 apparatus 5 for wastes as a fifth embodiment as viewed from its side. The  
 same reference numeral is used to denote identical or similar elements of  
 the thermal decomposition apparatus 5, 1, 3 and 4 of the first, third and  
 fourth embodiments.

25 The thermal decomposition apparatus 5 of the fifth embodiment  
 comprises the thermal decomposition device 3a and the decomposed gas  
 harm eliminating device 3b of the third embodiment combined as a unit as

in the fourth embodiment and is similar in composition to the thermal decomposition apparatus 4 of the fourth embodiment except that the thermal decomposition apparatus 5 is of a larger-scaled type and that the heating chamber 10 has a different internal <sup>arrangement</sup> composition. Thus, further  
 5 description of <sup>any</sup> the identical <sup>arrangement</sup> composition will be omitted and only their different structural portions will be described next.

Provided on top of the heating chamber 10 is a decomposed gas heating chamber 110 partitioned by horizontal and vertical partitions 16 and 18 of a heat <sup>ant</sup>resisting firebrick as in the decomposition apparatus 4 of  
 10 the fourth embodiment. The vertical partition 18 has a plurality of [through]holes 118 as inlet ports for the decomposed gas. A portion of the innermost refractory concrete layer 13a facing the outlet port 21 has a plurality of [through]holes 115 which place in fluid communication the heating chamber 110 and the outlet port 21, <sup>which</sup> also functioning <sup>5</sup> as an outlet  
 15 port for harmless gases.

The decomposed gas heating chamber 110 is separated by a plurality of (2 in FIG. 13) spaced partitions 116 of a refractory firebrick into a plurality of (3 in FIG. 13) subchambers 110a, 110b, 110c arranged  
 longitudinally (<sup>left to right</sup> right and left) in FIG. 13) within the apparatus 5. The  
 20 foremost subchamber 110a (the left one in FIG. 13) <sup>is in</sup> fluid communicates <sup>10</sup> through holes 118 with the heating chamber 10 whereas the rearmost subchamber 110c <sup>is in</sup> fluid communicates <sup>10</sup> through holes 115 with the outlet port 21. Each partition 116 has a plurality of [through]holes 117 provided at equal intervals through its length so as to place adjacent subchambers  
 25 in fluid communication.

In such arrangement, the thermally decomposed gases produced from the wastes are introduced from the heating chamber 10 through the

[through] holes 118 into the decomposed gas heating chamber 110, and thence pass through the subchamber 110a, [through] holes 117, subchamber 110b, [through] holes 117, subchamber 110c, [through] holes 115, and then discharge from the outlet port 21 to the outside.

5           The subchambers (110a, 110b in FIG. 13) other than the rearmost subchamber 110c are filled with a plurality of second balls 140 each in the <sup>shape</sup> ~~form~~ of a sphere, <sup>with the</sup> ~~which~~ balls ~~are~~ in point contact one with another. A second light emitting heater consists of the plurality of second balls 140.

10           The rearmost subchamber 110c is filled with a fiber-like active carbon filter 50. It is to be noted that no active carbon filter is provided within the exhaust pipe 23. The filter 50 may be replaced with a particulate active carbon filter. A filter of a material other than carbon may be used if it has sufficient absorptivity.

15           The sizes and shapes of the [through] holes 115, 117 and 118 are not <sup>so long as</sup> [especially] limited ~~if~~ the second balls 140 do not pass through those holes.

If the second balls 140 each take the form of a sphere, the shape of the [through] holes 115, 117 and 118 each <sup>preferably have a cross-section</sup> ~~take the form~~ of a triangle ~~preferably~~. The [through] holes 115, 117 and 118 each may take the form of a horizontal or vertical slit. For example, instead of using the partitions 116 with  
20 [through] holes 117, a plurality of ceramic pillars may be arranged in parallel to form a plurality of spaced slit-like holes 117, which serve to increase the opening ~~areas~~ of the [through] holes 115, 117 and 118. Thus, use of the plurality of slit-like holes is preferable when a large amount of decomposed gas flows ~~th~~rough them.

25           A pair of second electrodes consisting of two plate-like carbon electrodes (which are not shown in FIG. 13, but which have a similar composition to the pair of carbon electrodes 130 in the fourth embodiment)

are each disposed on a [respective one of both] sides of each subchamber filled with the second balls 140. Each carbon electrode has a carbon rod (which is not shown in FIG. 13, but which has a similar composition to the carbon rod 131 in the fourth embodiment) attached thereto and extending axially outward through the corresponding outer wall 11 of the decomposition apparatus 5.

In the thermal decomposition apparatus 5 (not shown in FIG. 13), the compositions of the carbon electrodes and rods, electrode units and openings are similar to those of the electrode units 157 and openings 152 of the thermal decomposition apparatus 4 of the fourth embodiment, and further description thereof will be omitted.

The decomposition apparatus 5 has three inspection openings 160 each provided above a respective [one of the] subchambers 110a, 110b and 110c and open in the upper surface thereof such that degrees of deterioration in the second balls 140 and the refractory concrete blocks are inspected and/or that, if necessary, the second balls 140 are replaced with another plurality of ones through the respective inspection openings.]

*The inspection openings 160 provide access for inspection and replacement of the second balls 140, and inspection of the refractory concrete blocks.*

In the decomposition apparatus 5, the size of the heating chamber may be adjusted depending on the kinds and quantity of the wastes to be decomposed. Furthermore, the number of subchambers each filled with the second balls 140 and the quantity of second balls 140 may be adjusted appropriately depending on the kinds and concentrations of the harmful substances contained in the decomposed gases.

A portion of the thermal decomposition apparatus 5 corresponding to the decomposed gas harm eliminating device 3b may comprise at least one of the same elements (a)-(d) as were described above with respect to the decomposed gas harm eliminating device 3b of the third embodiment.

A method of thermally decomposing the wastes, using the thermal decomposition apparatus 5, will be described next. The door 22 of the thermal decomposition apparatus 5 is opened, and the wastes are then cast into the heating chamber 10 so as to <sup>be</sup> placed over the plurality of balls 40.

5 The vacuum pump 51 is then activated to evacuate the thermal decomposition apparatus 5 to bring about a vacuum <sup>environment</sup> (state) (for example, of either a high vacuum of about  $6.7 \times 10^{-2}$  Pa or a lower vacuum of about 0.02-0.06 MPa). Thus, the plurality of balls 40 within the heating chamber 10 and the plurality of second balls 140 within the decomposed gas heating chamber 110 are also placed in the vacuum <sup>environment</sup> (state).

A required voltage is applied cross each of the first and second pairs of carbon electrodes (none of them are shown in FIG. 13) within the heating chambers 10 and 110 to cause electric discharges <sup>among</sup> [between] the first plurality of balls 40 and <sup>among</sup> [between] the second balls 140. [Since] the  
 15 respective discharge regions are at a high temperature of about 3000 °C and hence the wastes are thermally decomposed into gases as in the first embodiment and introduced through the respective groups of [through] holes 118 into the decomposed gas heating chamber 110. [Since] The discharge regions occurring <sup>among</sup> [between] the second balls 140 are also at a high  
 20 temperature of about 3000 °C, <sup>and</sup> the decomposed gases in contact with the discharge regions are also heated to about 3000 °C while the decomposed gases are passing through the subchambers (110a, 110b in FIG. 13). Thus, even when hydrocarbon compounds, carbon <sup>monoxide</sup> [dioxide], and harmful substances such as dioxin remain in the decomposed gases, they are  
 25 thermally decomposed into harmless gases.

Furthermore, the harmless gases pass through the filter 50. Thus, even when hydrocarbon compounds, harmful substances and metals still

remain in the harmless gases, they are adsorbed by the filter 50 without being [almost] discharged out of the thermal decomposition apparatus 5, and only harmless low molecular-weight substances are discharged out of the apparatus 5.

5           The large-scaled thermal decomposition apparatus 5 which comprises the thermal decomposition device and the decomposed gas harm eliminating device united as a unit thermally decomposes a large amount of waste compared to the thermal decomposition apparatus 4 of the fourth embodiment. Thus, the thermal decomposition apparatus 5 is greatly  
10   suitable for use in facilities (an eating house or restaurant, hospital or factory) which produce a large amount of waste compared to general households.

          The thermal decomposition apparatus 5 may be further increased in size. In this case, it is capable of disposing of a large amount of wastes,  
15   so that it is suitable for use in facilities (for example, a large-scaled factory) which discharge a large amount of wastes.

#### (Sixth Embodiment)

          In the thermal decomposition apparatus 1-5 of the first-fifth  
20   embodiments, at least portions of the inner walls (made of the refractory concrete layer 13a and the heat-resisting refractory firebrick layer 14) of the heating chamber 10 or at least portions of the inner walls (the refractory concrete layer 113a and heat resisting firebrick (not shown)) of the heating chamber 110 with which the first or second balls 40 or 140 are  
25   in contact may each comprise a plurality of convexities to thereby reduce the respective quantities of the first <sup>balls 40</sup> or second balls 40 or 140.

FIGS. 14 (a) and (b) are a vertical cross-sectional view

(corresponding to FIG. 3) and a horizontal cross-sectional view, respectively, of a lower portion of the heating chamber 10 of the thermal decomposition apparatus 1-5 for wastes. The same reference numeral is used to denote the identical or similar elements of the first and sixth embodiments.

5 The thermal decomposition apparatus of this embodiment is similarly in composition to that of the first embodiment and further description of the identical or similar structural elements thereof will be omitted and only different structural portions thereof will be described next.

10 The heating chamber 10 has on its bottom (made of a heat<sup>ant</sup>resisting<sup>ing</sup> refractory firebrick layer 14) a plurality of equally spaced parallel convex spacers of a triangular cross-section 15 extending by a length equal to a related pair of electrodes 30 perpendicular to the surfaces of the pair of carbon electrodes 30.

15 A plurality of balls 40 are disposed in groups between the respective parallel spacers 15. The number of balls 40 is reduced due to fact that the plurality of balls 40 are divided by the spacers 15 into a plurality of groups, and the use of the inclined surfaces 15a of the spacers 15. Thus, a quantity of electric power {to be used} is reduced<sup>providing a savings in operating costs</sup> economically.

20 The spacers 15 may have the same quality as the inner wall of the heating chamber 10 (refractory concrete or heat<sup>ant</sup>resisting<sup>ing</sup> refractory firebrick) or carbon such as high<sup>le</sup>density impermeability<sup>ity</sup> carbon or graphite. If the spacers 15 produce effects such as were mentioned above, the shape of the spacers 15 is not limited to a triangle in cross section.

25

(Seventh Embodiment)

A thermal decomposition apparatus 7 of this embodiment comprises

a group of intervening pillar-like impermeability<sup>le</sup> carbon spacers 19 of a semicircular cross section provided, respectively, between the inner wall (of the refractory concrete layer 13a and heat<sup>ant</sup>resisting refractory firebrick layer 14) of the heating chamber 10 and the plurality of balls 40 or between  
 5 the inner wall (of the refractory concrete layer 113a and heat<sup>ant</sup>resisting refractory firebrick layer (not shown)) of the heating chamber 110 and the plurality of second balls 140 in the relevant thermal decomposition apparatus 1-5 of the first-fifth embodiments. Thus, the plurality of balls 40 or 140 are not in contact with the inner wall of the heating chamber<sup>s</sup> 10  
 10 or 110, so that the probability that the inner walls of the heating chambers will be deteriorated or melted due to high temperature<sup>s</sup> produced from the plurality of balls 40 or 140 is reduced.

The intervening spacers 19 each may take the form of a pipe of a semicircular cross section or the form of a plate so as to cover a portion of  
 15 the inner wall of the heating chambers with which the plurality of balls 40 or 140 would otherwise contact.

FIG. 15 is a vertical cross-sectional view of the thermal decomposition apparatus 7. The same reference numeral is used to denote the identical or similar elements of the thermal decomposition apparatus of  
 20 the first and seventh embodiments.

The thermal decomposition apparatus 7 of the present embodiment is similar in <sup>arrangement</sup> composition to that of the first embodiment, and further description of the same similar structural portions thereof will be omitted and only different structural portions thereof will be explained next.

25 A plurality of intervening spacers 19 having a semicircular cross section are provided at predetermined intervals parallel to, and between, the surfaces of a pair of plate-like carbon electrodes 30 on the bottom (of a

heat<sup>ant</sup> resisting refractory firebrick 14) of the heating chamber 10. A second plurality of intervening spacers 19 having the same cross section are disposed perpendicular to the bottom of the heating chamber 10 along its lower inner portion (with which the plurality of balls 40 would otherwise contact) at the predetermined intervals between the pair of carbon electrodes 30 such that their flat surfaces are in contact with the inner wall or bottom of the heating chamber 10 with their cylindrical surfaces facing the heating chamber 10. The interval between any adjacent intervening spacers 19 is smaller than the diameter of one of the balls 40 used.

10 The spacers 19 are each made of high-density impermeability<sup>le</sup> carbon and graphite.

The spacers 19 may be disposed perpendicular to the surfaces of the pair of plate-like carbon electrodes 30.

The spacers 19 may include pillars of a circular cross section buried partly in the inner wall and bottom of the heating chamber 10 such that they protrude in 1/2-2/3 of their diameter into the heating chamber 10.

As described above, the plurality of intervening spacers of a semicircular cross section 19 are provided between the inner wall of the heating chamber 10 and the plurality of balls 40 to separate the inner wall and bottom of the heating chamber 10 from the plurality of balls 40. Thus, there is <sup>a very low</sup> substantially no probability that the inner wall and bottom of the heating chamber 10 will be deteriorated and/or melted by heat.

Since the intervening spacers 19 each have a circular surface, they are in point contact with the plurality of balls 40. Thus, no general electrically conductive state occurs, <sup>and therefore</sup> but electric discharges with high efficiency are achieved.

In addition, since the intervening spacers 19 in contact with the

plurality of balls 40 are each made of high density impermeability carbon and graphite, [so that] even when the light emitting heater 41<sup>is</sup> are heated to about 5000 °C<sup>or</sup> beyond 3000 °C, they<sup>space 19</sup> withstand that temperature.

The spacers 19 may be made of refractory concrete or heat<sup>ant</sup> resisting refractory firebrick as<sup>is</sup> in the material of the inner wall of the heating chamber 10. [In that case,] However, it has<sup>a</sup> only heat resistance<sup>only</sup> up to about 3000 °C.

In the present embodiment a voltage applied first is 400-500 V to thereby feed high power to the light emitting heater 41 to thereby increase their temperature to 5000 °C rapidly, at which temperature almost all materials and gases are decomposed<sup>to leave nothing</sup> including even ashes which includes the remains [leavings] in general incinerators [to leave nothing]. Since the decomposing<sup>tion</sup> speed is high, a large amount of wastes<sup>is</sup> continue to be decomposed continuously [constantly]. Once the heating chamber reaches 5000 °C, about 30 V<sup>the voltage can be reduced to</sup> will suffice for the voltage applied across the pairs of carbon electrodes and hence<sup>operation costs of</sup> the decomposition apparatus 7<sup>are</sup> is operated at low cost.

Even when the light emitting heater 41<sup>is</sup> are heated to a high temperature of about 5000 °C, the heating chamber 10 is in an oxygen<sup>free</sup> [less] or vacuum<sup>environment</sup> state. Thus, a position<sup>at a distance of</sup> distant from about 20-30 cm from the light emitting heater 41 is at a very low temperature and hence there is no need for cooling the thermal decomposition apparatus 7.  
<sup>without being tied to any theory, it is believed that</sup>  
The invention effectively uses the physical property of superconductivity that carbon and graphite exhibit at ultrahigh temperatures.

By applying the structures of the inner wall and bottom of such heating chamber 10 to the decomposed gas harm eliminating device 3b, the decomposed gases are made harmless efficiently.

A thermal decomposition apparatus 7 may be operated in a manner similar to that mentioned above in a state where a light emitting heater unit comprising the plurality of spacers 19 and the plurality of balls 40 as a unit is disposed between the pair of carbon electrodes 30.

5 An example of such <sup>an arrangement</sup> composition will be described with reference to FIGS. 16 and 17. FIG. 16 is a perspective view of a mount 80 on which the plurality of intervening spacers 19 are to be fixed. FIG. 17 (a) and (b) are a side view and a plan view of the mount 80 on which two groups of spacers 19 are fixed.

10 The mount 80 includes a rectangular frame 81 which has downward extending legs 82. Additional legs 82 may be provided at corresponding midpoints of respective sides of the frame 81.

A plurality of horizontally extending intervening spacers 19 of a circular cross section are fixed at predetermined intervals across a pair of parallel sides of the frame 81. A second pair of upward extending intervening spacers 19 are fixed at their lower ends parallel to each other to the pair of parallel sides of the frame 81. The interval between any adjacent spacers 19 should be smaller than the diameter of each <sup>of the</sup> balls 40. Each spacer 19 may have a semi-circular cross section. A plurality of balls 20 40 are placed on the plurality of horizontally extending spacers 19 fixed on the mount 80 in a space surrounded by the second plurality of spacers 19 to form a united light emitting heater unit comprising the plurality of balls and the first and second plurality of spacers.

Since the plurality of balls 40 are surrounded by the intervening spacers 19 disposed on the bottom and periphery of the mount 80, the plurality of balls 40 are not in contact with the inner wall <sup>or</sup> and bottom of the heating chamber 10, which therefore are <sup>prevented from</sup> hardly deteriorated <sup>10 in</sup> and/or

melted<sup>ing</sup> by the heat produced within the heating chamber 10.

Since the respective spacers 19 each have a circular cross section, they are in point contact with the balls 40. Thus, no regular electric conduction occurs, <sup>resulting in</sup> but electric discharges with high efficiency <sup>occur</sup>.

5 If the thermal decomposition apparatus 7 further has an opening in its front for moving the light emitting heater unit into and out of the heating chamber in addition to the openings 52 each provided on <sup>a</sup> respective one of the <sup>opposite</sup> sides of the decomposition apparatus 7, <sup>facilitating</sup> replacement of the plurality of balls 40 <sup>is greatly facilitated</sup> <sup>the advantage as does not provide for</sup> <sup>remains</sup> <sup>advantageously</sup> In addition, cleaning a small amount of <sup>leavings</sup>, and repair, inspection and replacement of the light emitting heater unit and the electrode unit 57 <sup>can be easily performed in three directions,</sup> <sup>advantageously</sup>.

15 The intervening spacers 19 are each made of high <sup>density</sup> impermeability <sup>le</sup> carbon and graphite. The material of the mount 80 is not limited as long as it has sufficient heat resistance. A simple iron plate will suffice for the mount 80 and hence repair, inspection and/or replacement of the light emitting heater unit is easily performed.

## 20 (Eighth Embodiment)

A thermal decomposition apparatus of this embodiment comprises a combination of each of the thermal decomposition apparatus <sup>1-5</sup> and 7 of the first-seventh embodiments with a plurality of pairs of horn-like or sharp-tipped rod electrodes 30a/130a each pair of horn electrodes 30a/130a <sup>being provided on a respective one of the corresponding pair of plate-like carbon electrodes 30/130 so as to extend axially inward perpendicular to the corresponding surface of the carbon electrode 30/130.</sup> FIG. 18 is a

perspective view of a pair of horn electrodes 30a attached to a carbon electrode 30.

In such arrangement, the number of points where the first/second plurality of balls 40/140 are in contact with the corresponding electrodes 30/130 increases to thereby increase the discharge efficiency and hence to obtain a high temperature of about 3000 °C in a shorter time than the other embodiments.

The horn-like or sharp-tipped electrodes 30a/130a may be replaced with corresponding polygonal pillar-electrodes although the latter is somewhat inferior in point contact compared to the former. The electrodes 30a/130a are not necessarily required to have a sharp tip <sup>but</sup> may take the form of a rod. Although a pair of horn electrodes 30a/130a are preferably attached perpendicular to the corresponding surface of a plate-like carbon electrode, they are not necessarily required to be so. The number of horn electrodes 30a/130a to be attached to one plate electrode is not limited, but <sup>preferably is</sup> [usually] about 1-5. The horn electrodes 30a/130a are usually <sup>made of</sup> the same in material as the carbon electrodes 30/130.

#### (Ninth Embodiment)

A thermal decompositions apparatus of this embodiment comprises an improvement to the thermal decomposition apparatus 1-5 and 7 of the first-eighth embodiments which in turn comprises at least portions of the inner walls (refractory concrete layer 13a and heat <sup>and</sup> resisting firebrick 14) of the heating chamber or at least portions of inner walls (refractory concrete layer 113a and heat <sup>and</sup> resisting firebrick (not shown)) of the heating chamber 110, with which the plurality of balls 40 or 140 contact <sup>and</sup> are composed of a monolithic refractory (refractory concrete or heat <sup>and</sup> resisting firebrick)

containing boron nitride.

Boron nitride has a melting point of 3000 °C and <sup>15</sup>has an electrical insulation <sup>or</sup> at high temperatures. Thus, the portions of the inner walls of the heating chamber 10 or 110 with which the plurality of balls 40 or 140 contact have improved heat resistance such that they ~~are hardly~~ <sup>resist</sup> deteriorated <sup>10 n</sup> ~~or~~ <sup>ing</sup> melted even at a high temperature of about 3000 °C.

[Instead of ~~the~~ <sup>a material</sup> monolithic refractory containing <sup>S</sup> boron nitride, a monolithic refractory containing at least <sup>one</sup> selected from the group <sup>consisting</sup> of boron nitride, niobium, silicon carbide, boron carbide, magnesium oxide, hafnium oxide, hafnium dioxide, and beryllium aluminum oxide.

A method of making, and a physical property of, first and second pluralities of balls 40 and 140 each made of graphite, <sup>and</sup> used in the above respective embodiments, will be described next in detail.

#### 15 (Example 1)

Fifty five weight parts of phenol resin was mixed with 45 weight parts of acrylic fiber having a length of 0.1-0.5 mm. Instead of the phenol resin, a polydivinyl benzene resin may be used. Instead of acrylic fiber, animal/plant fibers or a mixture of acrylic fibers and animal/plant fibers may be used. Those fibers such as the acrylic fibers were carbonized in the process of making the balls for the light emitting heater to become carbon fibers within the balls.

The above mixture of phenol resin and acrylic fiber was filled into a mold, and then heated and pressed sufficiently to cure the phenol resin to form spheres (for example, of a diameter of 33 mm). The molding may take the form of a hemisphere, rectangular parallelepiped or pillar. In the case of hemisphere, two hemispheres <sup>are</sup> ~~were~~ joined to form a sphere in this

stage. Those moldings may have holes or concavities into which desired ingredients are to be injected.

The moldings were then subjected to a flame resistance process at 250-300 °C, and then carbonized at 1000-1500 °C under an inert gas. The obtained carbon was then graphitized at 2000-3000 °C <sup>(to)</sup> and the graphite was then subjected to a sizing process (surface processing).

In the carbonization and graphitization, the half-finished product graphite was burnt repeatedly in an inert gas under an isotropic pressure of not less than 30 MPa in hot isostatic pressing (HIP) to increase the density of the graphite. The HIP is also a method capable of applying isotropic pressure to a sphere.

General graphite or carbon has <sup>on</sup> its surface and inside many pores, whose total surface is generally about 25 % of the whole surface area thereof. By the above-mentioned process, the total area of the pores <sup>on</sup> the surface and inside of the graphite was reduced to 10 % or less of the whole surface area of the graphite and according to circumstances, to 5 % or less.

By using a phenol resin as a filler, graphite having a relatively small number of pores was obtained. By further burning this graphite under pressure as described above, impermeability <sup>le</sup> graphite of a higher accuracy was obtained. [Such] Impermeability <sup>le</sup> graphite <sup>is resistant to corrosion by</sup> had corrosion resistance to almost all chemicals in a wide practical range of temperatures. It also had very high <sup>thermal</sup> heat conductivity compared to general corrosion resistance materials. It also had a high thermal stability <sup>with almost no adverse effects due to</sup> which was hardly affected adversely <sup>by</sup> rapid changes in the temperature thereof.

The quantity of the phenol resin to be added is preferably in a range of 10-60 <sup>percent by</sup> weight parts. When the quantity of the phenol resin exceeds 60 <sup>percent by</sup> weight parts, the specific gravity of the resulting

impermeability<sup>le</sup> graphite is reduced and <sup>gas products</sup> bubbles<sup>formed</sup> are liable to be produced within the graphite and/or unhardened <sup>gel-like</sup> portions [gel-like portions] are liable to remain within the graphite. In addition, in the carbonization and

graphitization, pressure is difficult to apply isotropically to the graphite, <sup>when phenol resin exceeds 60 percent by weight,</sup> If the quantity of the phenol resin is less than 10 weight parts, it is difficult to mold a mixture of the phenol resin and acrylic fibers as a unit. In order

to <sup>secularly</sup> prevent the occurrence of such problems, the quantity of the phenol resin to be added is preferably <sup>from about</sup> 20-55 <sup>percent by</sup> weight [parts]. It is to be noted that when the thermal shock resistance is considered, the quantity of the

phenol resin is only required to be sufficient to harden the acrylic fibers and should be preferably reduced.

<sup>This procedure produces</sup> [By such processing, the <sup>and</sup> balls for light emitting heaters<sup>each</sup>] in the form of a sphere <sup>and</sup> having a diameter of 30 mm [are obtained]. When the [half-finished] products <sup>subsequently</sup> take the form of a rectangular parallelepiped or pillar, they are <sup>into</sup> each ground <sup>into</sup> balls taking the forms of a sphere.

[Since] these balls are <sup>le</sup> each made of impermeability graphite, [they] have <sup>on</sup> absorptivity of not higher than that of rubber, a strength of two-three times that of general graphite, a hardness of not less than 65 (in Example 1, 68), a density of not less than 1.87 g/cm<sup>3</sup> (adjustable depending on a ratio

in mixture of fibers), a tensile strength of 16.7 MPa, a bending strength of 35.3 MPa, a compression strength of 98.0 MPa, a modulus of elasticity of not less than 12700 MPa, a coefficient of thermal expansion of  $3.0 \times 10^{-6}/^{\circ}\text{C}$ , a thermal conductivity of 151 W/m  $\cdot$   $^{\circ}\text{C}$ , and <sup>can withstand temperatures</sup> a heat resistance of

<sup>about</sup> 3000  $^{\circ}\text{C}$ . For chemical property, they exhibit excellent corrosion

resistance to chemicals having a strong acidity such as concentrated sulfuric acid and nitric acid, and chemicals having strong alkalinity such as sodium hydroxide. It is to be noted that when graphite is made from a

phenol resin, its alkalinity can be reduced somewhat. Results of a corrosion resistance test are shown in Tables 1-3. The term "all" used in a concentration item of each of Tables 1, 2 and 3 represents "all concentrations".

5 Since these balls for light emitting heater<sup>s</sup> are made of impermeability<sup>to</sup> graphite, as described above, they have the following<sup>flowing</sup> excellent characteristics:

- (1) they are<sup>resistant to</sup> hardly to be<sup>ion</sup> deteriorated<sup>ion</sup> by the chemicals contained in the harmful substances mentioned above;
- 10 (2) they are<sup>resistant to oxidation</sup> difficult to react with oxygen in the atmosphere and oxygen produced by decomposition of the wastes. Thus, they<sup>resist</sup> are difficult to<sup>ion</sup> deteriorate<sup>ion</sup> and<sup>resist production of</sup> produce few carbon monoxide and/or carbon dioxide;
- (3) they have a high strength,<sup>and resist grinding</sup> so that they are hardly ground to thereby have an high durability;
- 15 (4) they have only a small number of pores, and hence<sup>have low adsorption of</sup> are difficult to adsorb harmful substances mentioned above. [They adsorb few gas and hence hardly releases the adsorbed gas<sup>There is low adsorption and hence low desorption</sup> at high temperature<sup>if any</sup>];
- (5) they exhibit excellent electric and thermal conductivities; and
- (6) they have high resistance to<sup>thermal</sup> shocks due to rapid changes in the
- 20 temperature thereof.

The balls of Example 1 are usable<sup>environment</sup> even in the air without any problems. If they are used in a vacuum or oxygen<sup>free environment</sup> less state, they<sup>exhibit very low oxidation or deterioration</sup> are difficult to oxidize/deteriorate<sup>and an environment</sup> so that such state is preferable for use of such balls. Especially, in the vacuum state, the discharge efficiency is

25 high and high temperature<sup>are</sup> is easily obtained with a small amount of power for low operating costs [to thereby reduce a cost required for obtaining such high temperature].

(Table 1)

(Example 2)

10      [Since] ~~A~~ method of making [this example is] similar to that of  
Example 1, except for the materials to be used, <sup>and therefore</sup> further description of  
portions of the present method similar to those of the method used for  
making Example 1 will be omitted, <sup>mentioning only the differences</sup> and only different portions of the  
present method from those of [the method making] Example 1 [will be  
described next].

15      The balls for light emitting heater <sup>s</sup>each in the form of a sphere were  
made in a manner similar to [that used for making] Example 1 except that  
graphite powder (99.5 % of fixed carbon having an average grain size of 4  
 $\mu$ m) was used instead of the acrylic fibers of Example 1. <sup>as an alternative</sup> The graphite

powder may be replaced with carbon black powder, coke, charcoal powder such as Japanese Bincho charcoal powder, or a mixture of at least two of those materials.

The balls for light emitting heater, <sup>thus obtained</sup> exhibited  
 5 excellent characteristics similar to those of the balls for light emitting heater <sup>of</sup> Example 1.

(Example 3)

<sup>[Since]</sup> A method of making <sup>[this example is]</sup> similar to that of  
 10 Example 1, <sup>and therefore</sup> except for the materials used, <sup>further</sup> description of portions of the present method similar to those of the method used for making Example 1 will be omitted <sup>mentioning only the differences</sup> and only different portions <sup>of</sup> the present method from those of <sup>[the method of making]</sup> Example 1 <sup>[will be described next]</sup>.

15 Fifty five <sup>percent by</sup> weight <sup>[parts]</sup> of a phenol resin, 40 <sup>percent by</sup> weight <sup>[parts]</sup> of graphite powder (including 99.5 % of fixed carbon having an average grain size of 4  $\mu$ m), and 5 <sup>percent by</sup> weight <sup>[parts]</sup> of carbon fibers were mixed. <sup>As an alternative</sup> Instead of the phenol resin, a polydivinyl benzene resin may be used. <sup>As an alternative,</sup> The graphite powder may be replaced with carbon black powder, coke, charcoal powder  
 20 such as Japanese Bincho charcoal powder, acrylic fibers, animal or plant fibers or a mixture of at least two selected from those ingredients.

<sup>[By]</sup> Processing the mixture of the phenol resin, graphite powder and carbon fibers in a manner similar to <sup>[that used for making]</sup> Example 1, the balls for light emitting heater <sup>le.</sup> of impermeability <sup>produced</sup> graphite of high density, and  
 25 having a reduced number of pores were <sup>[each made]</sup> in the form of a sphere.

The balls, thus obtained, had excellent characteristics similar <sup>[to]</sup> those of the balls <sup>[of]</sup> Example 1 as well as an increased strength due to

inclusion of the added carbon fibers.

[Preferable quantities of phenol resin, graphite powder and carbon fibers to be added were 10-60, 30-89 and 1-10 weight parts, respectively.]

The balls for light emitting heater of various characteristics were made in

- 5 the combination of the respective ranges. When the quantity of the phenol resin exceeds 60<sup>percent by</sup> weight parts, <sup>problems</sup> troubles such as were described with reference to Example 1 can occur. When the quantity of the phenol resin is less than 10<sup>percent by</sup> weight parts, it was difficult to form a molding<sup>ed ball</sup> of phenol resin and graphite powder as a unit. [In order to surely preventing the above problems from occurring, the quantity of phenol resin to be added is more preferably 20-25 weight parts.] In terms of heat shock resistance, an added quantity of phenol resin required for hardening the graphite powder will suffice for making Example 3. Addition of a less quantity of phenol resin is more preferable.

The phenol resin is preferably in the range of about 10 to about 60 percent by weight. The graphite powder is preferably in the range of about 30 to about 89 percent by weight. The carbon fibers are preferably in the range of about 1 to about 10 percent by weight.

- 15 When the amount of carbon fiber to be added was less than 1 percent by weight part, the <sup>strength</sup> intensity of the resulting balls was not so improved, and [whereas] when <sup>the carbon fiber content</sup> it exceeded 10 weight <sup>percent</sup> parts, cracks were liable to occur in the resulting balls. [Three-seven weight parts of carbon fiber to be added are more preferable in terms of a tradeoff between the strength of the resulting balls and the degree of difficulty of crack occurrence.]

The carbon fiber content is more preferably from about 3 percent to about seven percent by weight.

(Example 4)

- Since <sup>and therefore</sup> a method of making [this example is] similar to that of Example 1, except for the materials used, further description of portions of the present method similar to those of the method used for making Example 1 will be omitted <sup>mentioning only the differences</sup> and only different portions of the present method from those of the method of making Example 1 will be described.

next]

Fifty five <sup>percent by</sup> weight [parts] of a phenol resin, 40 <sup>percent by</sup> weight [parts] of graphite powder (including 99.5 % of fixed carbon having an average grain size of 4  $\mu\text{m}$ ), and 5 <sup>percent by</sup> weight [parts] of tungsten powder (having an average grain size of about 1.0  $\mu\text{m}$ , a bulk specific gravity (no load) of 4.22, and a purity of 99.9 % or more) were mixed. <sup>as an alternative,</sup> Instead of phenol resin, a polydivinyl benzene resin may be used. <sup>as an alternative,</sup> The graphite powder may be replaced with carbon black powder, coke, charcoal powder such as Japanese Bincho charcoal powder, acrylic fibers, animal or plant fibers or a mixture of at least two selected from those ingredients. <sup>as an alternative,</sup> The tungsten powder may be replaced with titanium powder (having an average grain size of about 1.0  $\mu\text{m}$ , a bulk specific gravity (no load) of 1.5-2.0, and a purity of 99.9 % or more) or a mixture of tungsten powder and titanium powder.

[B] Processing the mixture of phenol resin, graphite powder and tungsten powder in a manner similar to that used for making Example 1, <sup>produced</sup> balls for light emitting heater <sup>le</sup> of impermeability <sup>and</sup> graphite of high density with a small number of pores <sup>shape</sup> were each made in the [form] of a sphere. Unlike Example 1, the balls of the present Example contained tungsten. In addition, the final step of the graphitization included heat treatment of the half-finished products at about 3000 °C in an inert gas.

Tungsten was heated at a temperature of about 3000 °C <sup>form</sup> to change to tungsten carbide ( $\text{W}_2\text{C}$ , a formula weight of 379.71, a density of 17.2 g/cm<sup>3</sup>, a Mohs' hardness of 9, an electric resist <sup>ance</sup> ability of 81  $\mu\Omega/\text{cm}$  (25 °C)). Titanium was also heated at a temperature of about 3000 °C to <sup>form</sup> change to titanium carbide ( $\text{TiC}$ , a formula weight of 59.90, a melting point of 3140  $\pm$  90 °C, a boiling point of 4300 °C, a density of 4.94 g/cm<sup>3</sup>, and an electric resist <sup>ance</sup> ability of 193  $\mu\Omega/\text{cm}$  (at room temperature)). When  $\text{W}_2\text{C}$  was heated

at a temperature of not lower than 2400 °C, its crystal form became a stable  $\beta$  type.

Titanium has a <sup>melting</sup>boiling point of 1675 °C, a boiling point of 3262 °C, and a density of 4.54 g/cm<sup>3</sup>. When it changed to titanium carbide, its melting and boiling points greatly increased and its density increased as well. Tungsten has melting and boiling points of 3387 and 5962 °C, respectively.

The balls for light emitting heaters of impermeability<sup>le</sup> graphite containing at least one of ditungsten carbide and titanium carbide had, in addition to the above-mentioned features (1)-(6) of Example 1, corrosion resistance, mechanical strength (a high hardness, a modulus of elasticity of 310000-440000 MPa) and heat resistance (to 3000 °C or more) [excellent compared to the balls of Example 1 which contained none of ditungsten carbide and titanium carbide]. In addition, they<sup>balls</sup> had a high electric conductivity (electric resistibility<sup>ance</sup> of not more than 70  $\mu\Omega$ /cm, (in the present example, 10  $\mu\Omega$ /cm)), and a high electric discharge efficiency.

The heat treatment of the half-finished products at about 3000 °C in the inert gas produced the following advantage:

- (a) after the heat treatment, the balls for light emitting heaters were not required to be subjected to a finishing process or step such as bright heat treatment<sup>for</sup> (of) polishing the surfaces of the balls; <sup>after use were substantially unchanged</sup>
- (b) the balls were hardly deformed in use; and
- (c) the heat treatment caused no pollution to the public.

[The quantities of phenol resin, graphite powder and tungsten powder to be added are preferably 10-60, 20-89, 1-20 weight parts, respectively.] [When the quantity of phenol resin to be added is out of the above range, troubles such as were described in Example 3 would occur.]

The problems, as described in Example 3, occur when the phenol resin is less than 10 percent by weight, or greater than 60 percent by weight.

The phenol resin is preferably in the range from about 10 to about 60 percent by weight; the graphite powder is preferably in the range from about 20 to about 89 percent by weight; and the tungsten powder is preferably in the range from about 1 to about 20 percent by weight.

[When more than 10 weight parts of the tungsten powder is added, the quantity of phenol resin to be added is preferably 20-60 weight parts in order to mold the mixture of phenol resin, graphite powder and tungsten powder as a unit.]

*When the amount of tungsten powder is greater than 10 percent by weight, the phenol resin is preferably in the range from 20 to 60 percent by weight.*

5           When the amount of tungsten powder to be added was less than 1 weight part, the mechanical properties, corrosion resistance and heat resistance were not substantially improved. When it exceeded 20 weight parts, the mechanical properties conversely deteriorated to thereby cause cracks in the resulting balls or reduce the processability of the balls. In  
10 order to improve the mechanical properties, corrosion resistance and heat resistance sufficiently, and to [surely] prevent the occurrence of the cracks in the balls and the problem of [ball] processability, the amount of tungsten powder [to be added] is preferably 5-10 <sup>percent by</sup> weight [parts].

15           [The problems of cracks in the balls and of the ball processability are liable to occur when the balls are each made of two hemispheres joined as a unit whereas when they are each molded in the form of a sphere from the beginning, the problems are difficult to occur.] [Thus, if the balls for light emitting heater each having holes and concavities are molded from their materials and tungsten powder is then injected into the holes and  
20 concavities, there is little probability that the above problems will occur even if the quantity of tungsten powder to be added exceeds 10 weight parts. Thus, if the quantity of tungsten powder to be added is between 10 and 20 weight parts, the above-mentioned method is preferably employed.]

*P The balls are preferably molded in the shape of spheres, when the balls are molded as hemispheres joined, problems such as cracking occur.*

*Plan an alternative, the balls may be molded with the phenol resin and graphite powder, and molded with holes and/or concavities. Subsequent to the ball formation, the holes and/or concavities are filled with tungsten powder and further processed. This is the preferred method when the tungsten powder is between about 10 and 20 percent by weight.*

25   (Example 5)

In this Example, a quantity of graphite powder used is larger than that of phenol resin. This Example is [exactly] the same as Example 1

except for the ingredients to be used. Thus, further description of the identical portions of Examples 1 and 5 will be omitted and only different portions of Example 5 from Example 1 will be described ~~next~~.

Twenty <sup>percent by</sup> weight ~~parts of~~ phenol resin, 70 weight <sup>percent by</sup> ~~parts of~~ graphite powder (including 99.5 % of fixed carbon having an average grain size of 4  $\mu\text{m}$ ), and 10 <sup>percent by</sup> weight ~~parts of~~ tungsten powder (having an average grain size of about 1.0  $\mu\text{m}$ , and a purity of 99.9 % or more) were mixed. [Instead ~~of phenol resin~~ <sup>an alternative</sup> a polydivinyl benzene resin may be used. <sup>in place of the phenol resin</sup> The graphite powder may be replaced with carbon black powder, coke, charcoal powder <sup>an alternative</sup> such as Japanese Bincho charcoal powder, acrylic fibers, animal or plant fibers or a mixture of at least two selected from those ingredients. <sup>an alternative</sup> The tungsten powder may be replaced with titanium powder or a mixture of tungsten powder and titanium powder.

By processing the mixture of phenol resin, graphite powder and tungsten powder in a manner similar to that used for making Example 4, balls for light emitting heaters <sup>be</sup> of impermeability ~~graphite~~ of high density with a small number of pores were ~~each~~ made in the form of a sphere.

The balls, thus obtained, had excellent characteristics similar to those of the balls of Example 4, and <sup>with</sup> a specific gravity of 1.5-1.8. It is to be noted that when tungsten powder having a specific gravity of 9.0 g/cm<sup>3</sup> (pressed under a pressure of 98 MPa) was used, the balls had a specific gravity of 2.66-2.7. In order to apply pressure to the balls to increase their density <sup>and</sup> <sup>improve the</sup> ~~to thereby give~~ impermeability ~~to them~~, tungsten powder having a specific gravity of 9.0 g/cm<sup>3</sup> is preferably used.

25

(Example 6)

This Example is ~~exactly~~ the same as Example 1 except for the

ingredients to be used. Thus, further description of the identical portions of Examples 1 and 6 will be omitted and only different portions of Example 6 from Example 1 will be described next.

Twenty <sup>percent by</sup> weight <sup>of</sup> phenol resin, 10-20 <sup>percent by</sup> weight <sup>of</sup> zirconium powder, and 60-70 <sup>percent by</sup> weight <sup>of</sup> graphite powder (including 99.5 % of fixed carbon having an average grain size of  $4\mu\text{m}$ ) were mixed.

<sup>In an alternative,</sup> Instead of phenol resin, a polydivinyl benzene resin may be used. <sup>As an alternative,</sup> The graphite powder may be replaced with carbon black powder, coke, charcoal powder such as Japanese Bincho charcoal powder, acrylic fibers, animal or plant fibers or a mixture of at least two selected from those ingredients.

A mixture of phenol resin, graphite powder and carbon fibers was then heated to 250-300 °C to cure the phenol resin, and burnt <sup>ed</sup> in the HIP at 1900 °C (higher than the melting point of 1857 °C of zirconium) to ~~react~~ <sup>heat</sup> the ~~cause its~~ carbon and zirconium ~~[to react with each other]~~ to form zirconium carbide (ZrC) (having a melting point of 3540 °C, a boiling point of 5100 °C and a Mohs' hardness of not lower than 8) of a high density with a small number of pores. It was then further burnt <sup>ed</sup> at 3000 °C in the HIP to produce balls for light emitting heater of impermeability <sup>le</sup> graphite ~~[each]~~ in the <sup>shape</sup> ~~[form]~~ of a sphere. [Since zirconium had a melting point of 1857 °C, the mixture was burnt in the HIP at 1900 °C higher than the melting point of zirconium.] When another metal is used instead of zirconium, it is ~~caused~~ <sup>heated</sup> to react with <sup>carbon</sup> ~~[carbide]~~ to form <sup>a</sup> metal carbide. Thus, the ~~[half-finished]~~ <sup>partially processed</sup> products are preferably burnt <sup>ed</sup> in the HIP at a temperature of not lower than the melting point of the metal.

The balls, thus obtained, had excellent characteristics similar to those of the balls of Example 1 as well as excellent heat resistance due to addition of the zirconium powder.

When the amount of zirconium powder to be added is less than 10 <sup>percent by</sup> weight ~~[parts]~~ <sup>do not appreciably occur</sup> great improvements in the heat resistance of the balls ~~[cannot]~~ be expected <sup>and</sup> whereas <sup>percent by</sup> when it exceeds 20 weight ~~[parts]~~ cracks are liable to occur in the balls as in Examples 4 and 5.

- 5 <sup>by an alternative,</sup> The zirconium powder may be replaced with niobium (Nb) or boron (B) powder or a mixture of at least two of those three materials. In addition, 10-20 <sup>percent by</sup> weight ~~[parts]~~ of at least one of tungsten and titanium powder may be added. A total quantity of those metal ingredients should not exceed 40 <sup>percent by</sup> weight ~~[parts]~~ <sup>percent by</sup> Forty weight ~~[parts]~~ or more of graphite (carbon black) powder and about 20 <sup>percent by</sup> weight ~~[parts]~~ of phenol resin as a binder are preferably added.
- 10

- When zirconium and niobium powder were together used, they reacted at high temperatures to produce a product <sup>exhibiting properties</sup> of superconductivity. Niobium reacted with graphite (carbon black) powder to become niobium
- 15 carbide which served to improve the heat resistance, hardness and electrical <sup>use as</sup> conductivity of the resulting balls for light emitting heaters.

- While in the Examples described above the materials were illustrated as being heated in a mold and pressed into spheres, they may be heated in a capsule and pressed into a rod, which may then be cut away
- 20 and ~~[then]~~ <sup>this</sup> ground into spheres. In ~~[that]~~ case, the capsule which contains the materials is evacuated and heated to cure the phenol resin. The temperature is then increased to 1900 °C or more to burn the capsule under a pressure of 49-294 MPa in the HIP, and further burn<sup>ed</sup> at 3000 °C in the HIP.

- 25 Even before <sup>the stop of</sup> burning at 3000 °C, the rod <sup>intermediate product is a</sup> includes <sup>comprising</sup> a carbon material of a very high density. Thus, <sup>the intermediate product may be</sup> if this rod is cut away and then ground into spheres ~~[those spheres are]~~ suitable for use as the balls for light emitting

heater<sup>s</sup> with <sup>low porosity</sup> a small number of pores.

Although in the case of the method of using the mold, two different steps which include molding the material into spheres and burning the material in the HIP are required to be performed. The method of using  
5 such capsule is only required to perform the HIP burning step, economically.

The material of the capsule is not especially limited as long as it does not react with the materials of the balls for light emitting heater<sup>s</sup> at high temperature. Usually, stainless steel, aluminum and iron are <sup>used to form</sup> [named]   
10 [as] the capsule material.

#### (Example 7)

An example of making balls for light emitting heater<sup>s</sup> using as a binder pitch (peteroleum, coal tar or pine pitch), will be explained next.

15 Graphite powder (which may be replaced with carbon black powder), pitch, metal powder, and a smallest amount of solvent were mixed and then charged into a column-type capsule of stainless steel, aluminum or iron up to about 80 vol % of the capsule capacity. The capsule was then  
evacuated to a vacuum state and then burnt<sup>ed</sup> at 1000 °C. <sup>Subsequently, the capsule</sup> [and further] burnt<sup>ed</sup>   
20 at 1900 °C or more at a pressure of from 49 to 294 MPa for carbonizing purposes. It was then graphitized at 3000 °C, and then processed into the balls for light emitting heater<sup>s</sup> of impermeability<sup>be</sup> graphite of a high density with a <sup>low porosity</sup> small number of pores.

The quantity of graphite powder used was not less than 40 weight <sup>percent by</sup> parts. The metal powder is at least one selected from the group <sup>consisting</sup> of tungsten, titanium, zirconium, niobium <sup>and mixture thereof</sup> [and boron powder, [and its total]  
The total <sup>of metal powder</sup> amount added was 10-20 <sup>percent by</sup> weight [parts]

<sup>the stop of</sup>  
 Even before burning at 3000 °C, the rod <sup>intermediate product is a</sup> includes <sup>comprising</sup> a carbon material  
 of a very high density. Thus, <sup>the intermediate product</sup> if this rod <sup>maybe</sup> is cut away and then ground into  
 spheres, <sup>low porosity</sup> those spheres are suitable for use as the balls for light emitting  
 heater with a small number of pores.

5

### (Example 8)

In the Examples 1-6 the pressurizing and burning steps were  
 illustrated as being performed <sup>under a blanket of air</sup> in the inert gas. If nitrogen gas is used as  
 the inert gas, the added metal ingredients are <sup>formed into a</sup> nitrided. Thus, the  
 10 strength, hardness and discharge resistance of the balls for light emitting  
 heater are increased.

Similar effects were also obtained by again burning the balls for  
 light emitting heater made in each of Examples 1-7 in a nitrogen gas  
 atmosphere at 1900-2000 °C.

15

## ABSTRACT

An inventive thermal decomposition apparatus for wastes comprises: a heating chamber for heating the wastes; an inlet port for introducing the wastes into heating chamber; at least one pair of electrodes provided within the heating chamber; a plurality of balls each taking the shape of a sphere whose primary ingredient is carbon, provided between the at least one pair of electrodes so as to produce an electric discharge when a voltage is applied across the at least one pair of electrodes; an outlet port for discharging out of the heating chamber gases into which the wastes are thermally decomposed; oxygen<sup>free</sup> or vacuum<sup>environment</sup> forming means for evacuating means for placing the heating chamber in an oxygenless or vacuum state such that the balls are placed in an oxygenless state.

According to the present invention, an inexpensive thermal decomposition apparatus for wastes is provided which thermally decomposes almost all wastes at a high temperature of not lower than about 3000 °C without producing any harmful substances such as soot, dust, chlorine compounds such as hydrogen chloride, nitrogen compounds such as NO<sub>x</sub> and/or dioxin.
